THE USE OF DIGESTIVE FERMENTS IN MEDICINE *

CHARLES G. STOCKTON, M.D.
BUFFALO

The primary digestion is accomplished through the action on the foodstuffs of certain ferments. The action *in the case of each and all of these ferments is that of* hydrolysis. Different foods require for their hydrolysis the attack of different sorts of ferments, and the organism is fortunately provided with a variety of these secretions.

It is somewhat remarkable that the several ferments operate unfavorably on each other. This is partly owing to the nature of the ferments and partly owing to the conditions under which they are secreted. Thus, ptyalin, an important factor in the digestion of starch, acts for the most part in the stomach previous to the free secretion of acid gastric juice, which inhibits the ptyalin; and the gastric ferments, in their acid medium, are in turn made inactive through the secretions entering the duodenum. It will thus be seen that the administration of digestive ferments as medicaments is open to physiologic objections. It cannot be denied that ptyalin, certain pancreatic preparations and some of the diastases are possessed of a certain amount of power in the conversion of starch into maltose and dextrin when thoroughly mixed with carbohydrate food at the time of ingestion. Practically the activity of all these substances ends as soon as the gastric secretion has become mixed with the stomach contents.

It would seem reasonable that when dealing with cases in which there is a very low gastric secretion, or none at all, these preparations would prove of material advantage to patients. It is presumable that they have some beneficial effects, but it is not considerable. At least such is the conclusion reached after the study of the digestion of patients treated with these ferments.

Not infrequently patients with low gastric secretion who are given extracts of pancreas, extracts of malt and other forms of diastase represent themselves as feeling better from the use of these substances. It is difficult to determine how much of this improvement is subjective, and how much of it owing to the extractive matter, bitter, or aromatic substances which may accompany the ferments in question.

Clinicians not infrequently take advantage of another means of assisting the digestion in patients who lack gastric secretion; that is, they attempt to favor the digestion of proteids by the administration of pepsin and hydrochloric acid. The question is, how much advantage is obtained by this plan? The French observers have interested themselves in the administration of gastric juice removed from the stomach of dogs through a fistula, and administered to patients suffering from lowered gastric digestion. The results are apparently far superior to those obtained by the administration of pepsin and hydrochloric acid. Nevertheless it can be shown by the removal of the stomach contents in those who are victims of achylia gastrica that appreciable, though very slight, digestion of proteids goes on in the stomach after the administration of pepsin and hydrochloric acid in full doses. In some instances the same result is obtained by administering hydrochloric acid alone.

As a rule the secretion of the gastric ferments and hydrochloric acid goes hand in hand. This is not invariable. A disproportion between the total acidity and the digestive power of the stomach has been shown by several observers. This occasionally appears in neurotic conditions.

In inflammatory states, the so-called catarrhal conditions of the stomach, accompanied by lowered secretion, the amount of hydrochloric acid and pepsin apparently occurs in natural ratio.

The great difficulty in obtaining better digestion through the administration of pepsin in lowered secretion lies in the fact that we are unable to administer hydrochloric acid in sufficient amount to satisfy the demands of the ferments. In order to bring about good digestion relatively enormous quantities of hydrochloric acid must be given, and this the patient resents. We should realize that, while the administration of pepsin and hydrochloric acid under such conditions is a move in the right direction, the actual help to gastric digestion is really very small.

The question arises what influence for good may exist in pepsin *per se*. May it not exercise some beneficial effects on the organism regardless of its special action in the stomach? I am not aware that this question has been answered. We occasionally find patients who insist that they feel great improvement from taking pepsin, though we may satisfy ourselves that this does not depend on any marked improvement in gastric digestion.

As to the matter of the effect of preparations of pancreas on intestinal digestion, the situation becomes still more confused. I have not been able to satisfy myself that intestinal digestion is improved by the administration of any ferments whatever. If asked to prove this I should have to plead my inability. I have been unable to recognize the improvement either in the observation of the patient or the study of the stools. Cooperation between the secretions of the duodenum, of the pancreas and the liver, not to mention that of the stomach, is a matter of so much intricacy, as shown by the recent studies of Pawlow, Starling and others, that one feels reluctant to claim good results from the administration of diastase or pancreatic extract.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

On the whole it must be concluded that the question of the administration of digestive ferments in medicine is complicated and is rendered the more uncertain by lack of precise knowledge as to what becomes of them in the digestive canal. In our present state of knowledge, or rather lack of knowledge, it behooves us to be modest in claiming either good effects or no effects from the administration of these ferments.

There can be no question that a large number of *preparations which have been placed on the market* are practically inert. Many combinations that are widely advertised, and presumably largely prescribed, are self-destructive, provided they are made as represented. That is to say, the various elixirs, etc., said to contain pepsin, pancreatin, hydrochloric acid, lactic acid, vegetable diastase, etc., are not only unphysiologic in theory, but by careful analysis made by the Council on Pharmacy and Chemistry of this Association, have been shown to be practically worthless so far as digestive activity is concerned.

This is not the least of many contributions to the enlightenment and assistance of the profession which have been made by the Association in recent years, and this seems to be a good occasion to express a recognition of the service.

436 Franklin Street.

ABSTRACT OF DISCUSSION

Dr. George Dock, New Orleans: My experience with the digestive ferments is rather unpleasant for those engaged in their sale. I think that Dr. Stockton was gentle in his reprobation. I have never prescribed digestive ferments. To be sure, some of my enthusiastic assistants have prescribed them, but never with any good results that I could see.

Dr. C. S. N. Hallberg, Chicago: It might be interesting to remark that in 15,000 prescriptions in the city of Philadelphia, representing about fifteen different pharmacists and one hospital, pepsin as such was prescribed 356 times, essence of pepsin 398 times, glycerite 15 times, the wine 20, the compound powder 18 and the aromatic 5. Pancreatin leads with 177 times. That means that the two main preparations of pepsin, that is, pepsin itself and the essence, were prescribed 750 times on 15,000 prescriptions. This shows that not all practitioners agree with Dr. Dock's theory.

Dr. Charles G. Stockton, Buffalo, N. Y.: I did not prepare this paper as a voluntary contribution, but at the request of the management, and I realize that it has practically nothing new in it. It is simply a belief perhaps too nihilistic, which I expressed as best I could.

Moscow Free from Cholera During Prevailing Epidemic.—P. Blumenthal contributes an article to the *Zeitschrift für Hygiene und Infektionskr.*, xliii, 199, 1909, calling attention to the brilliant results of the installation of a good water service in warding off cholera as evidenced in the experience at Moscow last year. During 1908 there were 9,000 persons attacked with cholera at St. Petersburg, while notwithstanding the constant communication with Moscow, there were only sixteen cases of cholera at Moscow during the year. Moscow used to have extensive epidemics of cholera, three in particular, in 1830, 1848 and 1853, having included respectively 8,798, 59,000 and 4,000 cases with the usual mortality of approximately 50 per cent. In 1893 a new system of water works was installed, providing the entire city with good spring water, supplemented in 1900 by an equal amount of river water passed through nine filters, after which the number of bacteria is much below 100 to the c.c., ranging from 5 in winter to 41 in June as the extremes.

THE REMOVAL OF TUMORS OF THE PITUITARY BODY BY AN INFRANASAL ROUTE

A PROPOSED OPERATION WITH A DESCRIPTION OF THE TECHNIC

ALLEN B. KANAVEL, M.D.
Assistant Professor of Surgery, Northwestern University Medical School
CHICAGO

The various operations designed for the removal of tumors of the pituitary gland in which entrance is made through the nose have all passed through the upper part of the nasal cavity.

After an extensive study of the anatomy and repeated operations on the cadaver, I have worked out the details of an infranasal procedure and herewith submit the details of the technic.

In general, two routes are proposed, the intracranial and the extracranial or trans-sphenoidal. The former has been suggested by Caton and Paul, Krause, Kiliani and Caselli, and put into use by Horsley and McArthur. In the main, however, surgeons are inclined to view that approach with disfavor owing to the difficulties and dangers incident thereto, and Braun is the only one of the recent contributors who maintains that the route is practicable. Certainly, a study of the anatomy and the reports of the pathology, present in the cases, distinctly favor the trans-sphenoidal route, for, while a few of the tumors rise in the sella turcica, in a great majority of cases they erode the floor and grow downward. This latter fact must not be lost sight of in considering the proper course to pursue, since we are dealing not with the normal anatomy, but with a pathologic condition, which in this case fortunately lessens the difficulties of the operation. I have worked over the various methods of approach to the sphenoid proposed by various men.

One of the simplest of the proposed methods of reaching the sphenoid base is by an incision passing between the base of the tongue and the angle of the inferior maxilla, but its difficulty is that the point of entrance is too far away for easy work and it is chiefly unsatisfactory since it strikes the sphenoid at an angle, and in a majority of the skulls I examined would necessitate an extensive removal of bone and even then be unsatisfactory.

The splitting of the superior maxilla, as suggested by König and Hertle after the method of Gussenbauer, is a severe operation and does not give any better access than the simpler methods.

The remainder of the operations have consisted in some method of turning the nose to one side or down and thus reaching the sphenoid after removing the ethmoid cells and turbinates and at times making even more extensive resections. Among these may be mentioned the operations of von Michel, Giordano, Löwe, Moszkowicz, von Eiselsberg, Schloffer, etc. Löwe made a longitudinal incision a little to one side of the median *line of the nose, cutting through bone and soft parts.* The two sides of the nose are then turned back and the ethmoid cells and turbinates removed, the septum being either deflected to one side or resected. The sphenoid cells are then opened.

Moszkowicz and Tandler proposed to make an incision along the side of the nose and to turn it to one side. The *operation then proceeds along the lines just described.* They proposed to secure more room at times by the removal of the nasal process of the superior maxilla and the under wall of the frontal sinuses. The operation was performed in two stages; the first part carried the operation down into the sphenoid cells as described above; a flap of skin was then secured from the forehead and turned in along the cribriform plate, the tip reaching into the sphenoid cells. This was done with the idea of preventing meningitis. At the second operation the floor of the sella turcica was broken down and the tumor removed. It may be remarked in passing that, aside from the dangers of the operation, the floor of the sella turcica is generally destroyed at the time the patient comes to operation.

Schloffer in his case turned the nose to the right, excised the turbinates, the ethmoid cells, and the septum, removed the inner wall of the left orbit down to the optic foramen and the inner wall of the antrum of Highmore with a portion of the nasal projection of the left superior maxilla and then removed the tumor through the sphenoid cells.

Hochenegg turned down the nose, removed the ethmoid cells, septum and turbinates, made a bone flap of the anterior wall of the frontal sinuses and then passed through the sphenoid cells.

Von Eiselsberg operated each time by turning down the nose by what he refers to as the *Stimmegabelschnitt* (tuning-fork incision), removing the anterior wall of the frontal sinuses, the ethmoid cells, turbinates and septum. Borchardt operated after Schloffer's method.

It is thus seen that the essential feature of all these operations consists in reaching the sphenoid cells by the supranasal route.

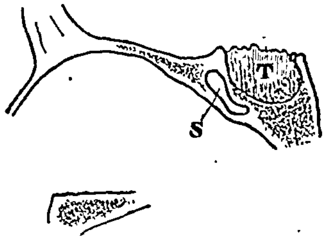

Fig. 1.—Finding on the *x*-ray plate of the tumor in a patient under observation.

Against this route is the great danger of meningitis arising through the cribriform plate, and the necessary removal of the ethmoid cells in addition to the turbinates with the attendant hemorrhage. Moreover, in von Eiselsberg's cases there was marked deformity following recovery. In favor of his operation was the fact that the distance from the surface to the sphenoid is slightly less, and, moreover, it seemed that one might have more definite landmarks to follow. This latter advantage I soon found was more apparent than real, since, owing to the downward curvature of the cribriform plate in two of my skulls, I was led to enter the sphenoid too low down. This will be seen by examining Figure 6.

In my search for a simpler method I was led to turn the nose up and thus follow a route to the sphenoid through the inferior part of the nares. I was surprised at the simplicity of the procedure, the good field it gave to operate through and the apparent security of the results. Moreover, it appealed to me because of the minimum of hemorrhage and the markedly lessened chances of infection.

The essential steps of the operation, therefore, are as follows:

The nose is turned up and entrance made into the inferior part of the nasal cavity; the septum is cut along its inferior part and its attachment to the perpendicular plate of the ethmoid. The middle turbinates are removed and the septum deflected to one side. We thus have a perfect view of the field of operation on the sphenoid. The sphenoidal foramina are located, and the interfering attachment of the perpendicular plate of the ethmoid and the vomer are bitten away. The anterior wall of the sphenoid cells is broken in, and by the aid of a Hajek-Schmithuisen punch forceps the sphenoid cells are opened up and the tumor removed as in any other procedure. It is essentially, then, an infranasal route.

By this method in nine cadavers I had no difficulty in opening the sphenoid cells and removing the floor of the sella turcica. In no case did I miss it and open any other part of the floor of the skull, an accident which did occur once during an operation by the von Eiselsberg method, when, following the roof of the nose as a guide, I was carried by its downward curvature under the sella turcica. Moreover, the technic was so simple as to take a minimum of time. The only real difficulty encountered was the variation in the sphenoidal sinuses, and this, of course, is attendant on any type of trans-sphenoidal operation.

A few of the practical points brought out by the cadaver work and study may be mentioned.

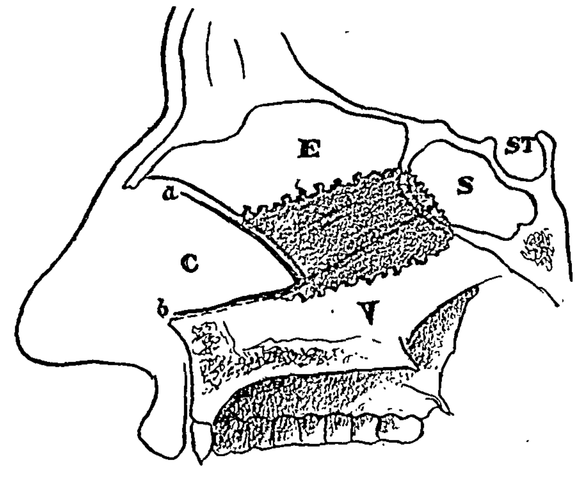

Fig. 2.—Line of incision (a-b) for the elevation of the cartilage (C). The perpendicular plate of the ethmoid (E) and the vomer (V) are shown as bitten away, as well as the anterior wall of the sphenoidal sinus (S).

In my cadaver work I made an incision around the lower half of the nose close to the crease at the alæ and close under the nares so as to have a minimum of scar. It may be necessary to excise the anterior end of the inferior turbinates. It is easily held in this position by the Jansen mastoid retractor. The deflected septum is held to one side with a Fraenkel nasal speculum, which holds the cavity wide open and yet does not interfere with the subsequent manipulations. Long, delicate yet strong instruments should be provided. The Hajek-Schmithuisen punch forceps is of great aid and it will be advantageous to have a narrow chisel with the end deflected at about 20° from the straight line. This is used in entering the sella turcica from the sphenoid. The attachment of the vomer to the sphenoid must be used as guide to the median line, since the septum between the sphenoidal cells is generally not in the median line and is asymmetrical in its relations. Many variations are noted in the sphenoidal cells. They may not be clearly separated from the ethmoid cells and it may be necessary to excise these latter. The cells vary greatly in size in different individuals. They may be no larger than peas, although this is uncommon, since they are generally of fair size. They may be extremely large. At times a horizontal septum divides them into four, and here it is difficult while operating to say whether you are

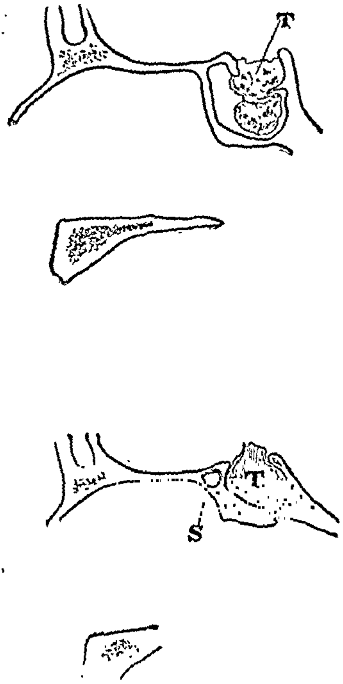

Fig. 3.—Tumors of the pituitary body, showing their relation to the sigmoid sinus. The upper drawing is from Zuckerkandl; the lower from Schloffer; the latter, and those in Figure 4, being from specimens in the museum at Prague

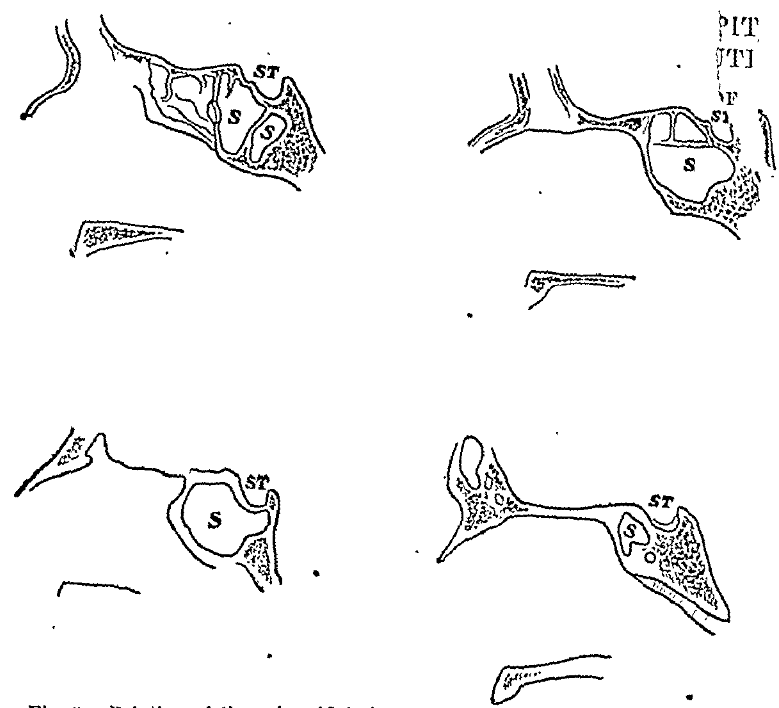

Fig. 5.—Relation of the sphenoidal sinus (S) to the sella turcica (S T) in various skulls.

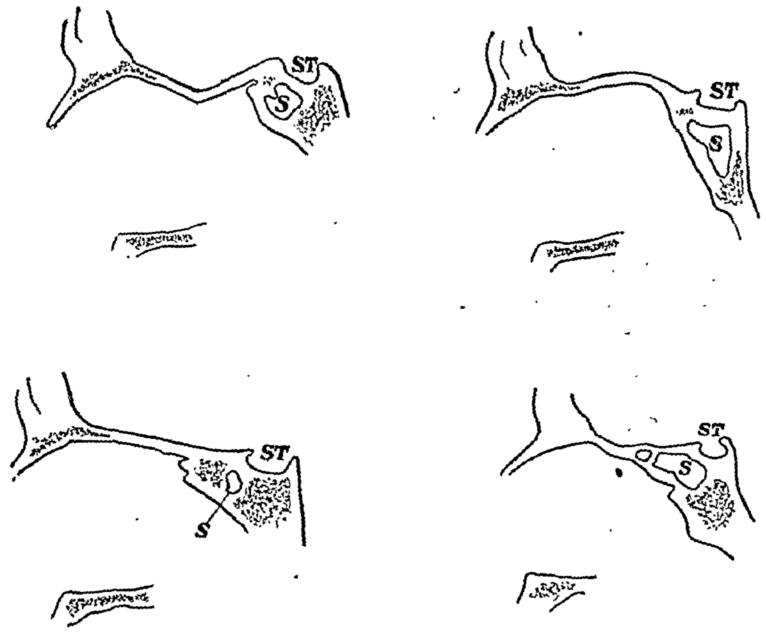

Fig. 6.—Relation of the sigmoid sinus (S) to the sella turcia (S T) in various skulls.

in the ethmoid or sphenoid cells. The sella turcica is also subject to great variation in size and position. These general facts may be seen from the drawings herewith shown, drawings made from my own cases and some redrawn from Zuckerkandl (Figs. 3-6). The changes in the relations due to tumors of the hypophysis are also shown in the drawings taken from various sources. Some idea of the relations may be secured from noting the position of the foramina. Zuckerkandl gives the accompanying table.

It will thus be seen that the roof of the sphenoid cells will lie approximately a centimeter above the foramina.

RELATIONS OF SPHENOIDAL CELLS TO FORAMINA

Height of Sphenoidal Sinus. mm.	Height of Foramen. From Bottom. mm.	From Top. mm.	Height of Sphenoidal Sinus. mm.	Height of Foramen. From Bottom. mm.	From Top. mm.
13	9	4	24	16	8
18	8	10	25	8	17
20	9	..	25	14	11
22	16	6	25	14	11
24	15	9	27	19	8

The distance from the bony entrance to the sella turcica should be measured on the x-ray plate. This information is of considerable aid while operating. It is normally about 8.5 cm. A good light is essential. The Kirstein or other head-light is satisfactory. The questions as to position of the head, packing the nasal cavity before the operation with adrenalin-soaked gauze, the type of anesthetic, etc., are not germane to my subject, except that one should consider favorably the rectal anesthesia as administered after the method of Professor Besley and Dr. Churchill. The anatomic work was done in the laboratory for experimental surgery of Northwestern University. I acknowledge the great help of Drs. F. Gurney Stubbs and H. M. Richter in developing the technic.

SUMMARY

The infranasal route is proposed in contradistinction to the supranasal route for reaching the tumors of the pituitary body. The technic in general consists in elevating the nose, cutting the cartilaginous septum, removing the middle turbinates, deflecting the septum, locating the sphenoidal foramina, biting off the intervening attachment of the perpendicular plate of the ethmoid and vomer, entering the sphenoid cells and thus reaching the floor of the sella turcica.

CYSTOCELE

A RADICAL CURE BY SUTURING LATERAL SULCI OF VAGINA TO WHITE LINE OF PELVIC FASCIA *

GEORGE R. WHITE, M.D.
SAVANNAH, GA.

Ahlfelt states that the only problem in plastic gynecology left unsolved by the gynecologist of the past century is that of permanent cure of cystocele.

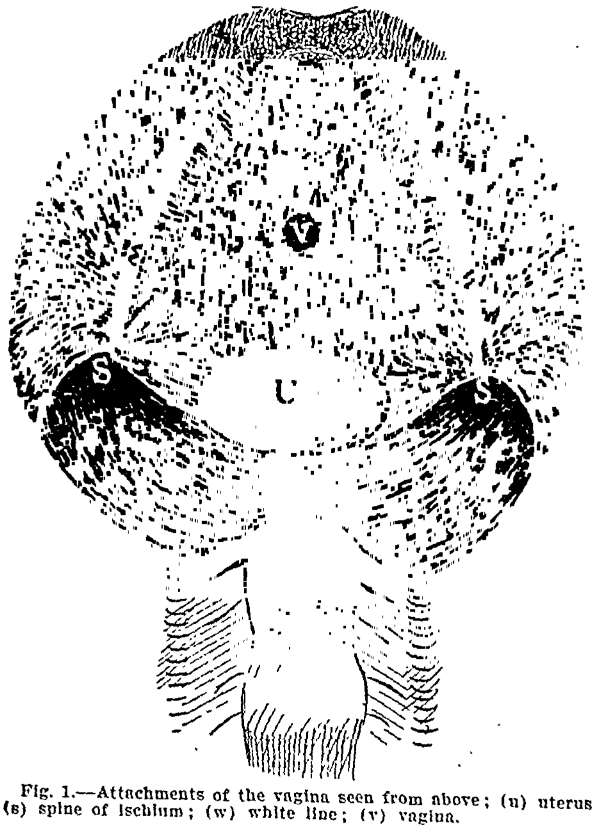

Fig. 1.—Attachments of the vagina seen from above; (u) uterus; (s) spine of ischium; (w) white line; (v) vagina.

That these cases recur after operation is too well known. The late Paul Numde states that all of his cases ended in failure and he had given up operating for that condition. The reason for failure seems to be that the normal support of the bladder has not been sought for and restored; but instead an irrational removal of part of the anterior vaginal wall has been resorted to, which could result only in disappointment and failure.

The support of the bladder may readily be determined in the cadaver by making a suprapubic incision and attempting to push the bladder out through the vulva. It will be found to rest on the anterior vaginal wall to which it is slightly adherent. If the bladder be pushed aside and an attempt made to push the anterior vagina wall back toward the perineum its support comes out very plainly. It is attached to the symphysis pubis and pubic bones in front, laterally to the white line of the pelvic fascia and ischiatic spine; and, above and behind, to the uterus. The uterus, being freely movable, is no important factor in the case and the real support of the vagina comes from its attachment to the white line of the pelvic fascia and especially a thick bundle of fibers attached to the spine of the ischium and radiating out on both the anterior and posterior surface of the vagina. If the fibers along the white line, and especially those originating from the spine, be cut across, the vagina falls down and can be pushed out of the vulva in the manner of a cystocele. It is, therefore, evident that a cystocele is caused by the breaking loose of the vagina from the white line which can readily occur during labor and especially in an instrumental delivery.

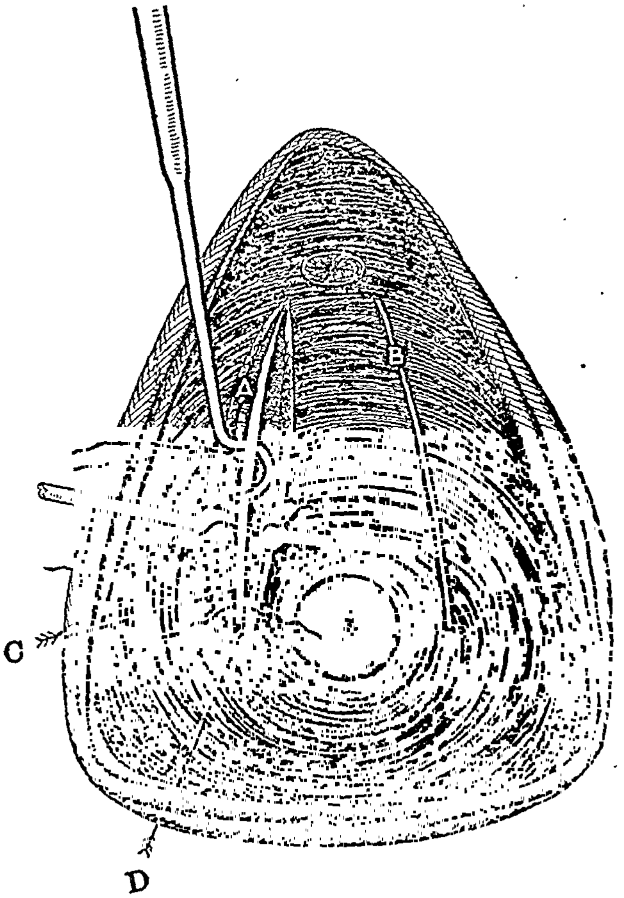

Fig. 2—Passing of sutures (a) back of the white line by Deschamp's handle-needle: two sutures in place; incision (b) from lateral sulcus of vagina to side of urethra; (c) white line; (d) spine of ischium.

I have recently had an opportunity to observe the actual occurrence of this lesion in a case of instrumental delivery for eclampsia, in which a laceration run-

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

ning along the lateral sulcus of the vagina laid bare the spine of the ischium, and separated the vagina from its attachments. Had the patient lived, she would undoubtedly have had a cystocele.

In another case of a young primipara delivered by forceps without any laceration, except a small tear along the lateral sulcus of the vagina, a complete cystocele developed within a month, although the perineum was intact and the uterus was in normal position.

In the treatment of cystocele the object is to reattach the vagina to the white line of the pelvic fascia, especially at its origin from the ischiatic spine, which can be done through the vagina without great difficulty.

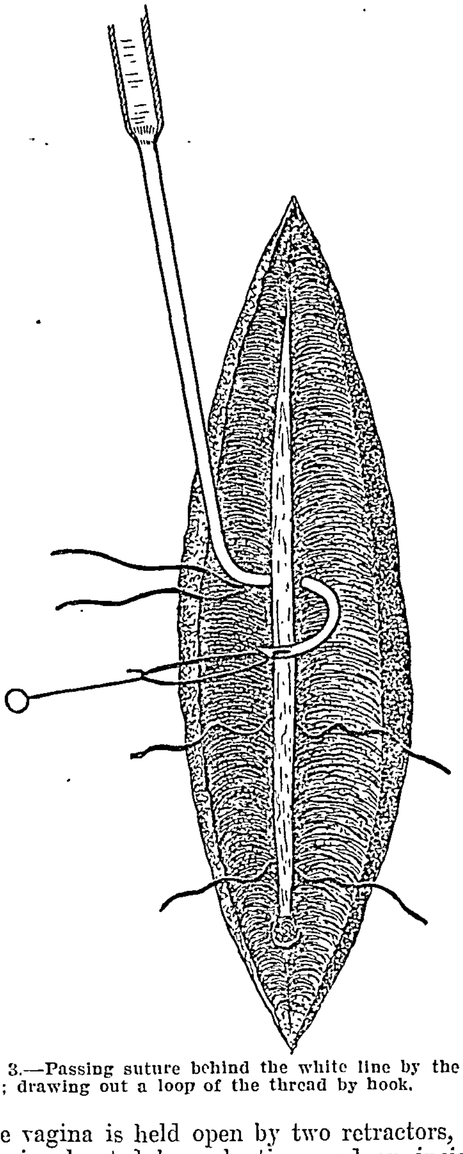

Fig. 3.—Passing suture behind the white line by the Deschamps needle; drawing out a loop of the thread by hook.

The vagina is held open by two retractors, the ischiatic spine located by palpation, and an incision from one to two inches long made through the mucous membrane, parallel to the white line, and extending well up the vagina. The bladder is separated from the vagina by blunt dissection until the spine of the ischium and white line are reached and can be felt uncovered beneath the finger. Hemorrhage is seldom troublesome and can be controlled by a few minutes' pressure. The sutures, which are of chromicized catgut, are passed under guidance of the finger by a Deschamps handle-needle.[1]

The first suture goes back of the white line just as it joins the spine of the ischium. The handle-needle is taken off, and each end of the suture threaded on a separate needle; one needle is passed from within out through the median edge of the incision, taking a firm hold on the vagina; the other needle is passed in a similar manner through the lateral edge of the incision. The two ends are then clamped and are ready to be tied. A similar suture is placed half an inch lower down on the white line, and when this is in place both sutures are tied, bringing the lateral sulcus of the vagina in contact with the white line of the pelvic fascia.

Should there be any prolapse at the outlet of the vagina, the incision may be extended down alongside of the urethra and the vagina sutured to the dense fascia covering the pelvic bone. The opposite side is treated in a similar manner and when both sides are tied the anterior vaginal wall is drawn up in a normal position, and has no tendency to sag, even when the patient coughs or strains. The vagina reaches across from one ischiatic spine to the other, without any tension; it collapses when the retractors are removed and normal relations of the parts are restored.

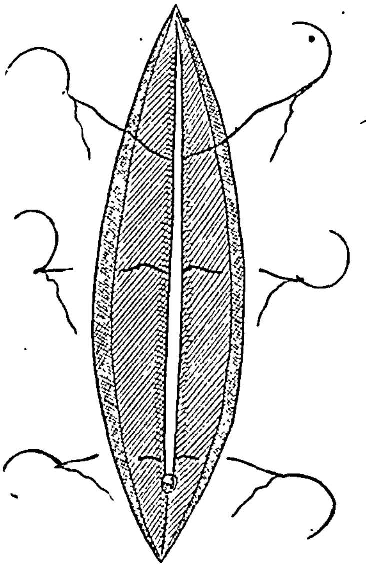

Fig. 4.—Suturing the lateral sulcus of the vagina to the white line.

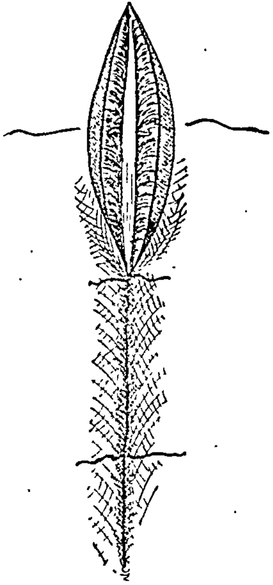

Fig. 5.—Closing the wound; two sutures tied.

The operation is always done in combination with other plastic operations, and does not interfere in any way with them, nor does it minimize the caliber of the vagina, which is a matter of importance should extensive denudations be contemplated for a rectocele.

The immediate effect is satisfactory. There is not much pain; dysuria, if present, passes off in a few days. The patients get up in from ten days to two weeks.

I have performed the operation nineteen times in the past three years, always in connection with some other plastic operation. No recurrence of the cystocele has taken place, so far as I have been able to determine, though some of the patients could not be followed.

The operation presents the following advantages:

1. The normal supports of the bladder and vagina are restored.
2. There is no sacrifice of tissue.
3. Recurrences are rare and are due to faulty technic rather than faulty principles.
4. The operation is done without interfering with any other plastic work about the vagina.

4 Liberty Street, West.

---

[1] I make use of a Deschamps needle, described by Charles Peck in his article on cleft palate, Annals of Surgery, January, 1906, xliii, 10.

ABSTRACT OF DISCUSSION

Dr. H. Grad, New York City: At the Woman's Hospital in New York we have passed through a series of stages in plastic surgery. It was in this place that Sims began his plastic surgery, followed by Emmet, Thomas, Peasley and others. We formerly operated there on a plan devised by Emmet of denuding the anterior wall of the vagina in cystocele with the addition of a suture Emmet devised. A denudation is made on either side of the cervix and also in the median line on the anterior wall of the vagina, and when these three denudations are brought together the cervix is pushed into the hollow of the sacrum. That was the first principle of a successful operation on the anterior wall as practiced in the Woman's Hospital. This operation was done for a great many years, but we had a great many recurrences. Within the past few years another method has been followed there, and that is the method of Dr. J. Riddle Goffe. In this operation a longitudinal incision is made from the urethra to the cervix on the anterior wall of the vagina and a transverse incision along the cervix. These two incisions open up the entire anterior wall of the vagina, the bladder is dissected off, which is a very important point, because the bladder wall becomes adherent to the anterior wall of the vagina in a way that is vicious. Dr. White did not mention cystocele where no traumatism has occurred. In the unmarried woman there is no traumatism, but a gradual loss of the support, and the result is cystocele. By dissecting off the bladder as practiced by Dr. Goffe, we find that we get absolutely perfect results. He sutures the base of the bladder to the anterior wall of the uterus with three fine catgut sutures to hold the bladder out of place. The pelvic fascia is brought together in the same manner as one does in operating for a hernia.

It seems to me that the operation described by Dr. White is a very good one because it is based on good principles, but I believe that unless the bladder is at the same time separated from the anterior wall of the vagina there will be some recurrences.

Dr. C. W. Barrett, Chicago: The principles on which cystocele is treated must be based on the fact that cystocele or rectocele, or prolapse of the uterus is a hernia through the pelvic floor, and we must take into consideration the supports of the pelvic organs and the abdominal organs as well. The viscera, including the pelvic organs, are supported by ligaments and then by a limiting wall, and that limiting wall grows in importance as it goes downward. The pelvic floor is in the unfortunate position of having to play fast and loose, of having to be a most important part of the abdominal wall, because it is the lowest, and it must allow the passage of the child's head which distends the soft parts of the pelvic floor to the extreme limits of the bony parts; and these muscles must again contract so as to serve as the most important part of the abdominal wall. When important structures run through the abdominal wall, as we see in the inguinal region, instead of running straight through, they run through one part, then along the wall obliquely and then through the remaining portion of the wall. In the lower animals, the canal being more oblique, we have less tendency to hernia. As the intra-abdominal pressure increases, the pressure of the internal layer is against the external layer. In animals that walk on all-fours, very little of the pressure comes on the perineal region. In the higher class of animals and in man the muscles which have no use as tail muscles form in the median line the levator ani muscle. Occasionally in an individual we see, without trauma of the pelvic floor, that the muscle presents almost no fibers meeting in the median line, so that no support is derived therefrom and a tendency to hernia is created by reason of atavism of the muscle. We find that the patient needs a perineorrhaphy just as badly as the patient who has had a traumatism of the pelvic floor. To cure cystocele and rectocele we must do several things: 1. Create a good strong pelvic floor, that does not depend on any skin operation nor on a mucous membrane operation. It is herniotomy; going in and getting hold of the levator muscle which has been formed in the upright animals, but which has been displaced by traumatism or which has never met in the median line. 2. We must put the vagina out of a perpendicular line so that the anterior segment rests on the posterior. 3. If the vagina is so loose that no matter how good a pelvic floor we make, it would gradually work out over the perineum, we must do something with the vaginal canal; and it may be that this method is a good one. I have had no reason to discard the method of taking out an eliptical piece in the anterior wall: not a scarification, but a deep dissection of the anterior wall and bringing it together. 4. We must not only do these two things, but we must put the uterus out of line with the vagina. If we leave the uterus in line with the vagina it will dissect its way down through the vagina again.

Dr. I. S. Stone, Washington, D. C.: I agree with Dr. Barrett that there are two very strong "floors," or a division of one floor into two. It is very easy to understand this if we make a dissection from below or above, that the upper plane of this floor, as well as the lower, has strong bundles of fascia which may be demonstrated. If any one will make this dissection they will never fail to utilize it in an operation for cystocele. I can not understand how anyone, after these several years of advanced pelvic work, can continue to use a method denudation. Suppose we have only this upper "floor," as Dr. Barrett has said. If the uterus be left in such a position with the small end forward it will eventually prolapse. But if the uterus be so placed that the fundus is forward and the cervix backward, and in addition to the cystocele operation a proper perineal operation be performed, the patient is cured.

Dr. A. Goldspohn, Chicago: About seven years ago I published an article, with illustrations of the technic, entitled, "Intrapelvic and Infravaginal Perineorrhaphy, Without Loss of Tissue." I am glad that correct anatomic principles are finally gaining ground, with the profession, in regard to this operation; because until recently, this operation was in most hands a very superficial and incomplete performance, merely a cosmetic affair, which really improved the condition of the woman very little. As I pointed out in my first article on the subject, a German first called attention to the correct anatomy of the levator ani muscle, and its important function in this regard. I have wondered for years why it was that his countrymen did not incorporate his correct anatomic principles in their surgical attempts at perineorrhaphy I was recently informed by one of them, that it was because they did not have buried suture material. But we have had absorbable sutures for a number of years and have been rather slow in this country in grasping the proper scope, of this operation, and in bringing an efficient technic into general use. Recently Dr. Barrett has become active in this matter, and he practically advocates the same principles, that I have contended for all these years. The play of normal forces in a woman's pelvis, is such, that when she strains, that is when intra-abdominal pressure is exercised, the pressure strikes the vaginal tube, sideways from above, the body of the uterus being during the same time, driven forward, in intensified anteversion. The anterior vaginal wall is driven against the posterior vaginal wall, which in turn is or should be driven against the pelvic diaphragm, the levator ani below. In that manner the vaginal tube is closed against the descent of anything through its lumen by evagination. The bridge of the levator ani muscle which normally passes from one side to the other, back of the vagina and in front of the rectum, is best restored when it has been injured, by temporarily raising the posterior vaginal wall, and then uniting the important structures by purely transverse buried sutures, and then adjusting the detached vaginal wall in folds on the new bridge.

Uterine prolapse in this country being almost altogether in women past childbearing years, or in those who are willing to surrender that function, can be treated very successfully as a rule, by combining a vaginofixation or a ventrofixation of the uterine body or fundus, (by a fibrofibrous union), with a thorough restoration of the anatomy of the levator ani muscle as a pelvic floor or diaphragm. Moderate cystoceles require no other treatment than the building up of such a normal support for them from below. When they are very marked or large, however, it is usually necessary to attack the anterior vaginal wall, also to give the bladder a new location higher up or on the fundus uteri, where it can not again invite the disorder, and to abbreviate the expanded anterior vaginal wall. The latter is better done *not* by resection, but partly at least, by sliding a flap of one side under that of the other side, after appropriate detachment, and denudation, thus doubling this wall, over the median area, where it was formerly most attenuated.

Dr. G. R. White, Savannah, Ga.: I have been surprised many times in working out this subject to follow the logic of many of the operations recommended for the cure of cystocele. *Everything* as recommended except repair of the anatomic supports of the bladder. The problem of keeping the bladder in place is solved in repairing the shelf on which it rests. Otherwise I do not see how we can expect to cure cystocele. The point of great importance is that the pelvic organs are a unit. It will not do to repair one part and let the others go and expect to get a cure. There is no use in repairing a cystocele and leaving a relaxed perineum and prolapsed uterus.

THE MACROSCOPIC AND MICROSCOPIC APPEARANCES OF STOMACH CONTENTS

J. W. WEINSTEIN, M. D.
Attending Physician to the Gastro-Enterologic Department of the Vanderbilt Clinic and the Medical Department of the Sydenham Hospital Dispensary
NEW YORK

The subject of the macroscopic and microscopic appearances of stomach contents, especially the former, is one that has been neglected by gastrologists. The moment the examiner secures the contents he pours them immediately into the filter on the funnel for the chemical examination. I have to meet yet the man who carefully examines the stomach contents in gross and then makes notes of the macroscopic findings. Even the best text-books on the diseases of the stomach are almost silent on the subject. I myself can judge much better about the anatomic condition of the stomach from looking at the stomach contents than from the results of the chemical examination. I will illustrate by an example.

Here is a specimen of stomach contents that shows on chemical examination the following: Free hydrochloric acid, 30; total acidity, 60; lactic acid, 0; starch digestion, erythrodextrin; pepsin and rennet ferments normal; biuret positive. What would be the inference? Cannot tell, as everything seems normal. One glance, however, at the stomach contents will establish the diagnosis of the case. The contents present the following characteristics: It spouted out with great force, like a fountain of the stomach-tube. There is a large quantity of it. It is very watery. Very little bread in it. Small round granules (starch) are falling to the bottom. Anything like this makes the case clear at once. It is a case of hyperacidity.

Here is another example: Stomach contents on examination show free acidity of 37; total acidity, 73; lactic acid, 0; starch, amylodextrin; pepsin and rennin, normal; biuret, positive. What is the inference? Nothing distinctive. The case, however, is clearly one of chronic gastritis of the acid variety. And on gross examination the contents show it at once. There is a lot of mucus in the contents embedded within the food. Contents are rather profuse and fairly fluid, and I would, therefore, surmise this to be a case of acid gastritis.

The negative part of the examination is just as important as the positive. A patient presents himself and tells of his illness, which has come on him rather suddenly. He has previously been in perfect health. For past few weeks he has had a variety of dyspeptic symptoms, with some loss of flesh and strength, loss of appetite, etc. The diagnosis of cancer of the stomach naturally flashes through the physician's mind, and he gives the patient a test breakfast. The chemical examination of the contents gives a normal result. Would any one, in the face of that history, assert that there is no cancer? I hardly think so. If, however, the stomach contents are examined macroscopically and found to consist of a clear, thin, milky emulsion, this being supplemented by a negative microscopic examination (and I will point out later what is understood by a negative microscopic picture), I would not hesitate a moment in pronouncing this case to be free from cancer of the stomach. I shall proceed now to point out the characteristic features of the macroscopic and microscopic pictures of stomach contents in normal state and in disease.

NORMAL STOMACH CONTENTS

In order to establish fixed clinical pictures we must have a standard. The stomach contents must be extracted always after a certain time and after a fixed uniform meal. It will never do to compare the appearances at one time of a carbohydrate meal and next time of a meat meal, as the two meals will vary considerably in their appearance. Nor does the same meal look alike at different periods of digestion. Fortunately the Ewald test breakfast is marvelously well adapted to the purpose. Although I am in a habit of giving each stomach patient two meat meals as well as two Ewald test breakfasts, and I have, therefore, had the opportunity of examining as many meat meals as I have examined test breakfasts, I have not learned to judge of stomach contents consisting of a meat meal with the same certainty as of an Ewald test breakfast.

A normal test breakfast, when extracted three-quarters to one hour after it is eaten gives a uniform white milky emulsion. The particles of bread are very tiny and they are all of almost uniform size. The contents are neither too thick nor too fluid. One or two ounces are secured without difficulty either by expression method or by employing an aspirator. There is hardly any odor to it. On standing it will separate into two layers which will be almost even in volume, the bread being at the bottom and a rather turbid liquid at the top. There is no mucus to be seen in it in gross. Its color is white, but may shade off into a very faint yellowish tinge. Having made these observations I proceed next to pour the contents into the filter. I notice that the contents pour uniformly. There is no large aggregate of masses bound together. There is not much of adherence between the individual particles of bread; a very slight, almost inappreciable quantity of mucus. The contents filter with a fair rate of rapidity and in five to ten minutes we get 5 to 10 c.c. of contents filtered through.

Microscopic Examination.—A drop of the unfiltered stomach contents is put on a large glass slide and spread out evenly to a very thin layer with a glass rod. The unstained specimen is very unsatisfactory for microscopic examinations and the keenest observer will confound small starch granules, fat globules, yeast cells, cell nuclei and blood cells if they should happen to be there. (Blood cells are extremely uncommon in stomach contents, as they are digested by the gastric juice and lose their identity.) I have, therefore, discarded the unstained smears entirely.

The most satisfactory way of examining it is to use a solution of iodin and potassium iodid in the following proportions: potassium iodid, 0.1; resublimed iodin, 0.05; distilled water, 100. Gram's iodin may be used, but it is too concentrated and stains the mucus a bluish tinge. The iodin solution stains all the starch, which constitutes the bulk of the drop, blue or violet, according to the degree of the digestion of the starch, while all cellular elements, muscle fibers, yeast, sarcinæ, are tinged lemon-yellow color. Bacteria are not stained by it at all. This stain gives a beautiful and very satisfactory picture. The iodin evaporates quickly, however, and on working for fifteen or twenty minutes over the slide the colors fade, which can be remedied, however, by adding another drop of the solution: the colors are then restored. The solution must be kept in a glass-stoppered bottle, as the iodin will evaporate through both cork and rubber: will turn from the normal wine color of the solution to a straw color which then has no staining properties at all.

Normal stomach contents, when stained after the above method, will show large numbers of granules of varying size. They will all be dark blue or violet, which will alter with the degree of starch digestion, the latter circumstance, however, depending solely on the degree of the acidity of the stomach. The salivary ferment, the ptyalin, is always reliable and capable of carrying on the digestion of the starches with utmost satisfaction. It works, however, only in an alkaline, neutral and even faintly acid medium. According to Chittenden and Smith, it acts best when there is just acid enough to saturate the proteins present. This acid is called combined acid, as it enters into a chemical combination with the food. When there is acid present in excess of the affinities of the proteins present, i. e., above the degree of saturation, the acid remains free and is called free acid. It is this free acid that hinders the action of the salivary enzyme. It is obvious that in hyperacidity the rate of the secretion, the quantity of the acid containing gastric juice and the concentration of the acid cause the free acid to appear early in the digestion, and this checks the activity of the ptyalin. This is what gives the difference in coloration of starch with the iodin. The less the effect of the amylolytic enzyme the deeper does the iodin stain the starch and *vice versa.*

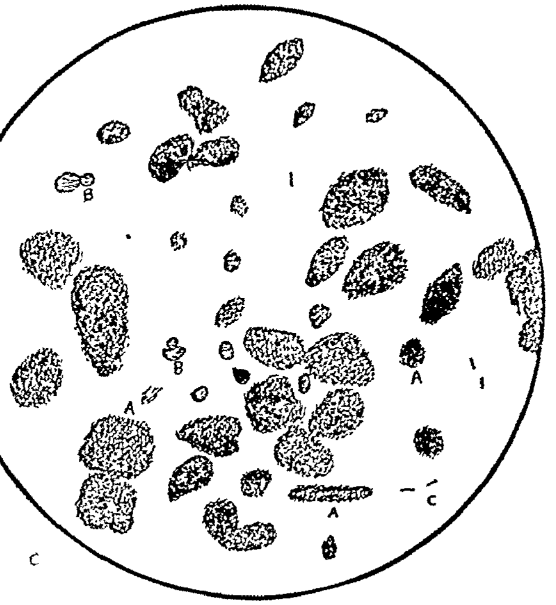

Fig. 1.—N. F.: Normal stomach contents. Test meal, stained with iodin solution; A, starch; B, yeast cells; C, micro-organisms. Leitz No. 7 objective; Ocular No. 2.

Besides the starch granules, a few yeast cells will be encountered. Yeast cells resemble very closely red blood cells, and the inexperienced eye will take them for such. They are almost of the same size. All red cells are of the same size, however; while yeast cells vary considerably, some being smaller and others being larger than a red cell. The main differential point is that yeast cells are oval, only rarely round. They are mostly situated in pairs. They are stained of a deeper lemon color by the iodin solution than red cells. In general red cells are a great rarity in stomach contents, while yeast cells are most frequent inhabitants of the gastric contents; occasionally an epithelial cell, just a few micro-organisms, cocci and bacteria (No. 7 Leitz). A bit of mucus may be met here and there.

The Stomach in an Empty State.—In fasting condition the stomach is contracted with the two walls lying in apposition to each other and no secretion is present. This is the view held by most writers, although some authors oppose it. We often, however, meet cases in which the introduction of the stomach-tube into the jejune stomach brings forth a few drams of fluid. This may have been left from the former meal. It may consist of swallowed saliva, or it may consist of duodenal secretion regurgitated through the pylorus. Some bile-stained fluid is of very common occurrence in the jejune stomach and this would imply regurgitated duodenal contents. The pylorus does not seem to be tightly closed when the stomach is empty. Boas[1] is of the opinion that the constant presence of bile in the stomach points to a stenosis of the descending portion of the duodenum. I have never found any acid present in these small quantities of secretions obtained from the fasting stomach, except in cases of Reichmann's gastrosuccorrhea. I have never tested them, however, for the presence or absence of enzymes.

By washing a fasting stomach we get off a good many exfoliated epithelia, bacteria and mucus, and from these a good deal of useful information may be secured on microscopic examination. I have examined the centrifuged sediments of the washings and will point out the results. In a normal stomach the washings are almost negative. Here and there an occasional cell is seen and some mucus and mucous corpuscles.

This completes the picture for normal, physiologic stomach contents. Anything beyond it either quantitatively or qualitatively is pathologic.

PATHOLOGIC STOMACH CONTENTS

Hypersecretion, Hyperacidity, Hyperchlorhydria.—The change in the character of the secretion is evident from the moment the tube passes through the cardia. The stomach contents rush through with a sudden gush and several ounces are obtained in a moment. On inspection the contents are seen to be profuse, very watery, with very little solid matter, possibly no food at all or heavy round little granules, like granules of sand, falling to the bottom. There is a marked acid odor. On standing, a very thin layer of solid granules appears at the bottom, with a large quantity of liquid over it. At times a small layer of thin bread particles float to the top, thus forming three layers: solids at bottom, liquid in the center and a thin layer of very light bread particles permeated by gases floating to the top. I will discuss later the significance of this. The contents filter very readily, almost like water through the filter-paper.

It is this profuse, watery condition, with or without the small, sand-like, starchy granules falling to the bottom, that makes the diagnosis of hyperacidity, no matter how low the figures for free, combined and total acidity should be. The explanation is obvious. Although the gastric juice be not concentrated and it contain not much hydrochloric acid in each individual cubic centimeter of stomach contents, the quantity of gastric juice being large, the total quantity of hydrochloric acid is necessarily high.

---

[1] Boas: Deutsch. med. Wchnschr., 1891, No. 28.

I employ this method of inspection exclusively in diagnosis of hyperacidity and never try to extract all the stomach contents. I consider this latter method both cruel and inaccurate. The test meal, as a rule, is being given to patients who are not accustomed to the use of the tube, and we ought to be perfectly satisfied if we get enough contents to yield after filtration about 10 or 15 c.c. for examination. It is a great torture to such a patient to try to empty the stomach completely, and, more than that, it is an impossibility to empty such a stomach. It is a very difficult task to perform even in a perfectly tolerant stomach. I will advise any skeptic who may doubt these latter words of mine, after he washes out the patient's stomach and he is convinced that the stomach is perfectly empty, to put the patient on a couch, have the patient relax himself and to splash the patient's stomach vigorously; he will elicit a very marked splashing. He will appreciate then how hard a task it is to empty a stomach completely.

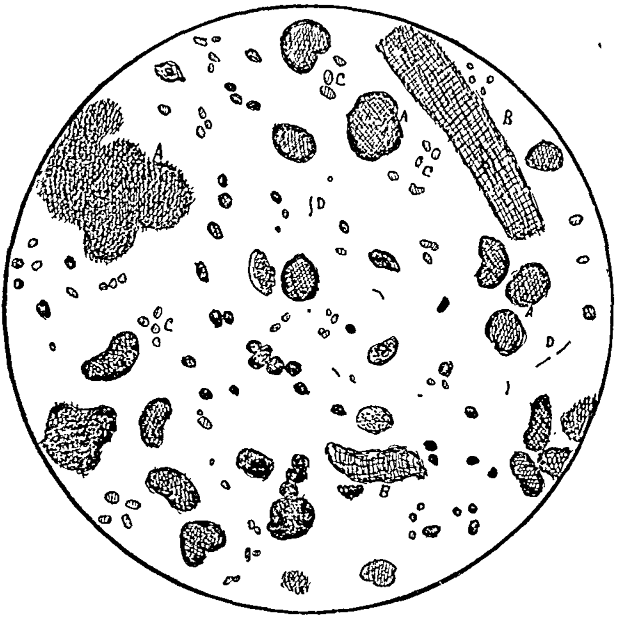

Fig. 2.—M. A.: Hyperacidity. Meat meal, stained with iodin solution; A, starch; B, muscle fibers; C, yeast cells; D, micro-organisms. Leitz No. 7 objective; Ocular No. 2.

Microscopic Appearance: The starch granules are of large size. They stain deep blue or black with the iodin solution. Yeast cells are present in abundance, much more than in normal stomach contents. A good many bacteria float around. This latter fact would be contrary to the general teaching of physiologists, that one of the functions of the hydrochloric acid in the stomach is as a bactericide. My studies in the microscopy of the stomach contents have shaken my faith considerably in this doctrine. It is my belief that the real bactericidal power of the stomach lies in its motility. When the motility of the stomach is normal, the micro-organisms are not so abundant, it matters not whether the acidity is below or above par; while on the other hand, even in the most marked cases of hyperacidity, such as we often meet in benign obstructions of the pylorus, the bacterial flora flourishes to stupendous proportions.

In case of a meat meal the muscle fibers are seen in hyperacidity to be very well digested, the striæ of the muscle fibers being almost obliterated.

The microscopic appearance of stomach washings from the empty stomach presents the same features as does that of a normal stomach: a few epithelial cells here and there; also some mucus and mucous corpuscles.

Gastric Fermentation.—I do not mean to classify this as a distinct disease. It is merely a single pathologic feature which occurs in a variety of gastric diseases, and it is appropriate to point out how this can be recognized by the stomach contents.

The stomach contents, in case of fermentation, when put in a beaker or bottle, separate into three layers: a layer of food at the bottom, a layer of turbid liquid in the center and a third layer on top. This layer consists of thin fermented particles of food permeated by gases which float them to the top, mixed with some mucus and also fat. We must differentiate this topmost layer of food from a mere layer of fat which has been ingested and which floats to the top. There is often a very offensive odor to the contents. The most frequent occurrence of stomach contents of such a character is in cases of motor insufficiency due to obstruction, mostly benign, and at times malignant, and also cases of atony of the stomach. It is often encountered in cases of hyperacidity, this probably being due to some fermentation within the stomach, owing to its retarded digestion of starches occasioned by the hyperacidity, since the ferment of the saliva—the ptyalin—works only in a neutral, faintly alkaline or faintly acid medium.

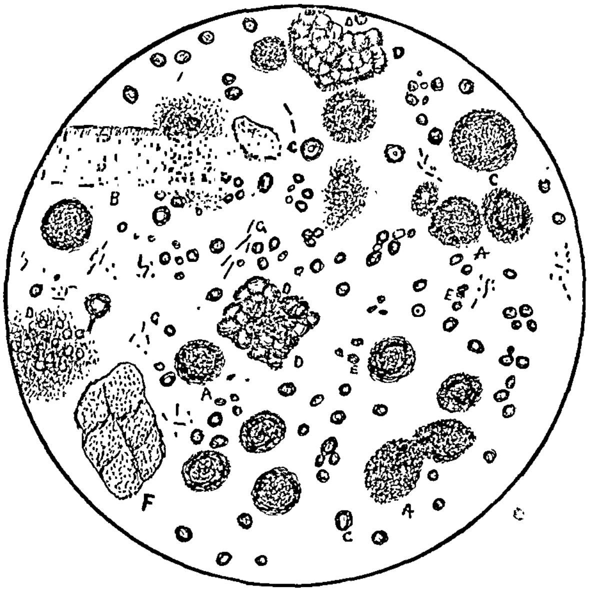

Fig. 3.—M. P.: Benign obstruction of the pylorus. Test breakfast. stained with iodin solution; A, starch; B, muscle fibers; C, fat; D, sarcinæ ventriculi; E, yeast cells; F, vegetable cells; G, micro-organisms. Leitz No. 7 objective; Ocular No. 4.

Gastric Ulcer.—The stomach contents may contain fresh blood, a phenomenon, however, which is seldom met. More often the contents have the appearance denoted by the classical name "coffee-grounds." "Coffee-grounds" are a cleavage product of the blood brought about by the gastric digestion. The coloring matter of the blood—the hemoglobin—through the enzymatic action of the gastric or pancreatic secretions, is converted into a protein body named globin and a ferruginous coloring matter, hemochromogen, which latter, in the presence of oxygen, becomes quickly oxidized into hematin. It is this hematin that imparts that characteristic color of coffee-grounds. Microscopically the red and white corpuscles can be made out but with great difficulty, since they become digested by the gastric juice, which is, as a rule, very active in cases of gastric ulcer, as these cases are accompanied by hyperacidity.

In interpreting the meaning of coffee-grounds one must be very careful, as the patient instead of the regular test meal may take coffee, and, what is worse, may try with all his might to deceive the doctor. The microscopic examination of coffee-grounds being of no value on account of the loss of the identity of the red and white corpuscles which can be made out but with great difficulty in such cases we have to resort to a chemical test, such as the hemin test, etc. A very satisfactory and simple test, indeed, and the one which I employ is this: To equal parts of chloroform and turpentine are added one or two drops of fresh tincture of guaiac. This is shaken; some of the solution to be tested is added and the mixture shaken. In the presence of blood the mixture turns blue. I wish to caution the reader not to rely too much on the presence or absence of blood, whether in gross or microscopically, in the diagnosis of ulcer of the stomach, as blood is not often met in the stomach contents in such cases. In cases of carcinoma of the stomach this is a much more common phenomenon. In ulcer, black stools should be rather looked for than blood in the stomach contents.

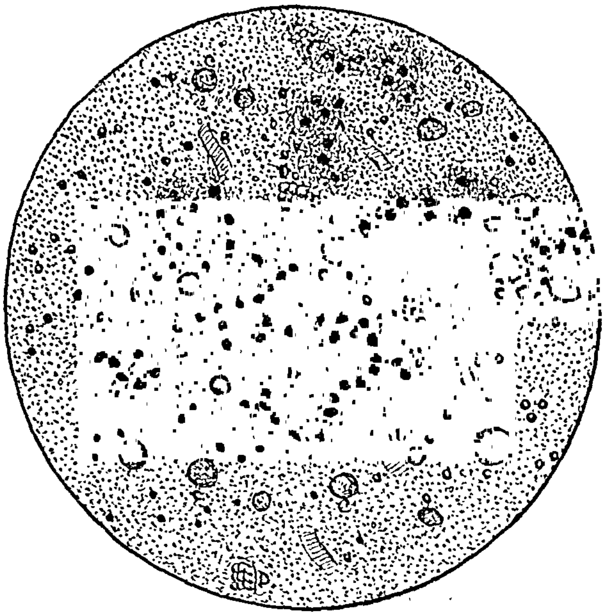

Fig. 4.—M. P.: Benign obstruction of the pylorus. Test meal; A, starch; B, muscle fibers; C, fat; D, sarcinæ ventriculi. Leitz No. 3 objective; Ocular No. 4.

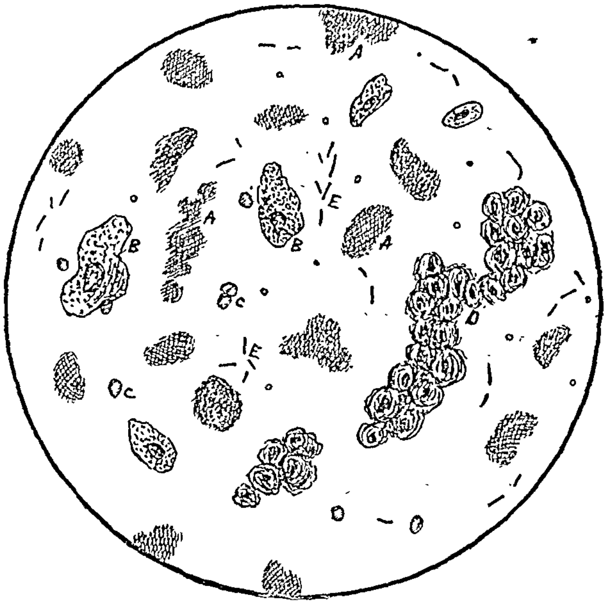

Fig. 5.—G. C.: Chronic gastritis. Test breakfast; A, starch; B, epithelial cells; C, yeast cells; D, mucous corpuscles forming mucus; E, micro-organisms. Leitz No. 7 objective; Ocular No. 2.

Motor Insufficiency.—The stomach contents usually have a gray, dirty look. A lot of fat globules float on the surface. Elements of food not included in the test meals are often recognized; especially skins of fruits are left behind and are easily recognized. The mixture emits a strong, rancid, butyric acid odor. It separates readily into three layers, solids at bottom and top with liquid in the center.

Microscopically we find starch granules stained blue by the iodin solution; muscle fibers (if the patient eats meat); fat globules in large numbers. The fat globules vary a good deal in size and appearance. There are large numbers of them as small as a red cell or a yeast cell and even smaller and some very large ones. The small ones, indeed, resemble red cells or yeast cells very much, and the only way to recognize them is, first, that the fat globules do not stain with the iodin solution, while the red and yeast cells do stain a light yellow color, and, second, that we find a large number of other globules of the same character, but of larger and manifold shapes. Fat is better identified with a low-power lens such as a 3 or 4 Leitz than with a higher power. The fat globules are of various shapes from round to oval, elongated and even gyrate figures. There is another form of fat globules which are met especially in obstruction cases and which look not unlike raspberries. They stain a very pale yellowish color with the iodin stain. These are undoubtedly fat globules that have undergone certain lypolytic changes, the exact nature of which, however, I have never succeeded in learning.

Another element encountered in motor insufficiency consists of the sarcinæ ventriculi. They look like bales of hay and are found in two forms, a larger and a smaller one. They are mostly met in motor insufficiency of benign origin. They are never seen in cancer. Oppler has injected pure cultures of them in carcinoma, and in twenty-four hours they all disappeared. Richter[2] reported a case of obstruction of the pylorus caused by a tumor formed by large aggregations of sarcinæ ventriculi. I have found it extremely useful in differentiating between an obstruction of benign and an obstruction of malignant origin. These cases are very trying, indeed, as they have most of the factors in common. There is the palpable tumor of the pylorus, there are the peristaltic movements of the stomach, there is the stagnation of food, there is the vomiting, there is the same loss of flesh and strength. The acidity is very often of little help, as in pyloric carcinoma the acidity is very often high. How are we to differentiate between the two conditions? A very good way is the microscopic examination. Presence of sarcinæ with absence of Boas-Oppler bacilli means benign condition. Presence of Boas-Oppler bacilli and absence of sarcinæ mean a malignant condition. In looking over my clinical material for the past few years I find only one case.

---

[2] Richter: Virchow's Arch. f. path. Anat., 1887, cvii, 198.

Case 1.—A. M., female, aged 35, presented a typical history and appearance of carcinoma, and yet large numbers of sarcinæ were found in the stomach. There was a good-sized palpable tumor in the stomach. The examination of her stomach contents showed the following: Free hydrochloric acid varying between 4 and 20; total acidity, 48 to 92; no lactic acid; starch digestion—erythrodextrin. Gross examination: Contents looked gray and were of foul odor. Unfortunately the case passed out of my observation and I could not learn the ultimate fate of the patient. That case certainly looked malignant, but was it not rather a case of sarcoma than carcinoma?

Another case is the following:

Case 2.—F. T., female, over 50, presented marked peristaltic movements and a lot of sarcinæ were found in her stomach contents. Here free hydrochloric acid was 40 to 50; total acidity, 70 to 76; lactic acid, 0. The patient was operated on at the Roosevelt Hospital. The pathologist's report inclined more towards a benign condition.

In general in motor insufficiency the microscopic examination is very often of great utility, as will be shown by the following case:

Case 3.—I was requested by a colleague to extract and examine a test meal. The patient was an elderly man and it was the hardest thing to persuade him to have a stomach-tube passed. The patient was given an Ewald test breakfast in the morning on an empty stomach. It required a good deal of suasion and humoring to have the patient submit to the ordeal, although the stomach contents were withdrawn without any difficulty. The chemical examination showed somewhat higher figures than normal. On microscopic examination I found a large number of muscle fibers and large numbers of sarcinæ ventriculi with numerous micro-organisms. The patient ate meat on the previous day; it was evident that the case was one of motor insufficiency and the sarcinæ pointed to a benign obstruction. Here we have accomplished through the microscopic examination a great deal, especially since the patient would never submit to any more tubing of his stomach to carry out the stagnation test.

The large number of various micro-organisms, irrespective of the acidity, is another factor found in cases of motor insufficiency. Yeast cells are in abundance.

I cannot refrain here from expressing my opinion about remarks that I often hear made at medical meetings by stomach specialists about the great value of finding microscopically residual food as an early diagnostic means of pyloric obstruction. The conception is both erroneous and fallacious. If there is any obstruction at the outlet of the stomach, it is not the microscopic particles that will meet the obstruction first, but the big chunks of food will be left behind. The analogy with esophageal obstruction is striking. In the early stages of obstruction of the esophagus it is not the liquid foods, but the solid foods that cannot go through. Soup, milk, etc., go through very easily, and these liquids certainly contain microscopic particles of food. Milk contains fat globules. It is only in the last stages, when the esophageal stricture becomes impermeable, that the liquids cannot get through. The same holds true of obstruction of the pylorus. I admit that in some early cases of pyloric obstruction in the morning on a fasting stomach one may find microscopically particles of food left from the supper from the previous evening, which will point to an interference with the motility, but in such a case we have a much more reliable criterion, namely, examination of the patient after a full-sized meal seven hours later, when any normal stomach will be empty, while in a case of motor insufficiency that stomach will contain a great deal of food. The stomach will succeed in grinding down and pushing through this food in twelve or thirteen hours during the night, with the patient in a recumbent position, merely leaving a turbid residue which microscopically will prove to consist of food granules. It is obvious that this method of finding a great deal of food in seven hours is a much more reliable criterion than finding microscopic particles entangled in the rugæ of the stomach wall twelve hours after a meal.

Chronic Gastritis.—The macroscopic appearance of the stomach contents is diagnostic. The stomach contents are very thick, very scanty and contain a lot of mucus. In advanced cases the contents are so thick and tenacious that they represent one mass of mucus. It is the most difficult thing to fish this mucus out of the stomach. It can very seldom be taken out by the expression method, but it must be aspirated by an aspirator. There is very little gastric juice secreted by the stomach in such cases and the contents filter with the utmost difficulty. The bread is not in a state of fine division or emulsion, but consists of considerable sized morsels, just like bread that was only chewed and spit out. In less advanced cases considerable gastric juice is present. The gastric juice is usually of a yellowish color; the bread floats in it, just as if it were simply bread macerated in water instead of the almost white, very finely, uniformly divided particles forming an emulsion of normal stomach contents. Chronic gastritis is one of those conditions of gastric disease in which one look at the contents by the experienced eye diagnoses with certainty the presence or absence of the disease. The picture I have just depicted is pathognomonic of it. It matters not what the acidity is. Once there is mucus present, the mucus being thoroughly incorporated with the food (which differentiates it from mucus coming from the nasopharynx) it is a case of chronic gastritis. At times we find in carcinoma some mucus, as the cancer brings about a secondary gastritic process in the stomach, but the histories of such cases are so much at variance that no difficulty in diagnosis need arise. I met lately a case in which the contents looked thin, watery and a large quantity of it was secured, with very little solids in it, and it looked like a typical hypersecretion case. On putting it into the

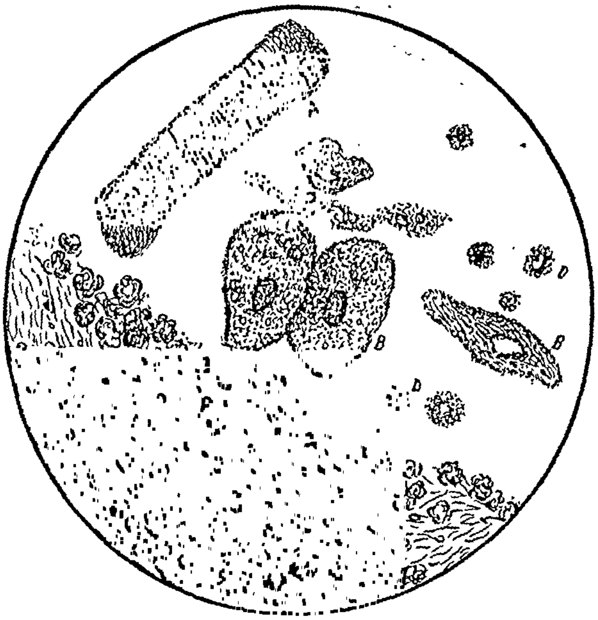

Fig. 6.—E. R.: Chronic gastritis. Washings from fasting stomach; A, muscle fibers; B, epithelial cells; C, a mass of mucus; D, mucous corpuscles. Leitz No. 7 objective; Ocular No. 4.

filter, however, I noticed some stringiness in it. It proved not to contain any free hydrochloric acid and this was thin mucus and not gastric juice, as first supposed. This is the only one of its kind I ever saw.

The surest way of recognizing mucus, when not present in large quantity, is by pouring the stomach contents from one vessel into the other or into the filter for filtration, when the particles of food are seen to be held tenaciously together in a stringy, sticky mass. Sometimes the whole quantity secured is rolling down *en masse;* while in the absence of mucus the particles of food show very little cohesive properties and each one separates readily from the other. The mucus of the stomach is found in two distinct forms. One consists of glassy, swollen and sticky lumps. The other consists of white flakes, strings or shreds. The difference in this appearance depends on the presence or absence of free hydrochloric acid. The first variety is seen in cases of anacidity, the second variety is present in cases of normal or hyperacidities. To differentiate mucus of the stomach from that of the nasopharynx, the stomach mucus is intimately associated and mixed with the food, while pharyngeal mucus is seen as isolated balls, it is purulent and often foamy.

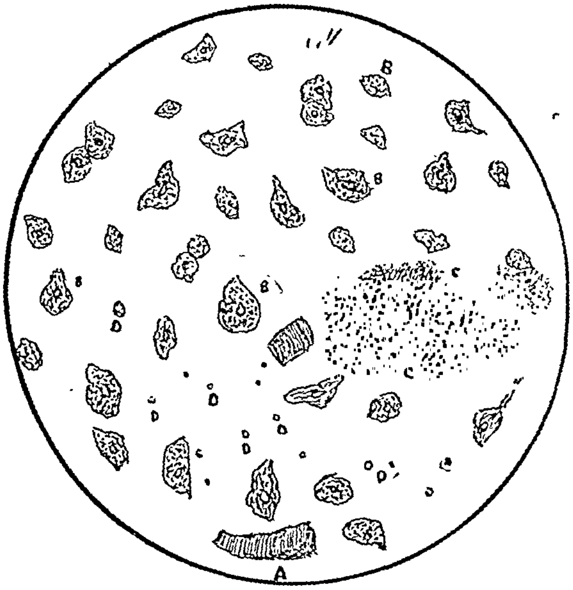

Fig. 7.—E. R.: Chronic gastritis. Washings from a fasting stomach; A, muscle fibers; B, epithelial cells; C, mucus; D, mucous corpuscles. Leitz No. 3 objective; Ocular No. 4.

Microscopic Examination: On microscopic examination, chronic gastritis presents a characteristic picture which can be differentiated from all other stomach diseases, except that in some cases carcinoma resembles it. The starch is but faintly stained with the iodin solution. The muscle fibers, if the patient took a meat meal, present very marked striæ, as they are unchanged, not having been acted on by the gastric juice, which is of very low acidity and of very poor enzyme content. The contents are full of mucus, which under the microscope is recognized as dark, stringy masses holding entangled in their meshes large numbers of epithelial cells and mainly round cells resembling leucocytes. Large numbers of epithelial cells are seen throughout the field, and micro-organisms. It is this picture of the mucus with the large number of round and epithelial cells that make up the pathognomonic picture of chronic gastritis, and there is only one stomach disease that may resemble it, namely, carcinoma of the stomach.

This microscopic picture can be employed as a very reliable guide to differentiate the grave diseases of the stomach with anatomic changes in the mucosa (ulcer excepted), such as gastritis or carcinoma, from the neuroses of the stomach. A picture like this points most decidedly to a condition attended by changes in the gastric mucosa, while the absence of this picture assures us either that there is nothing the matter with the stomach at all or that the stomach is afflicted with a disturbance of its nervous apparatus. It has served in my hands time and again for this purpose with elegance and precision.

The microscopic appearance of the washing of an empty stomach is equally characteristic of its condition. We find a lot of mucus, large numbers of epithelial cells, round cells in large numbers and especially round cells looking like leucocytes, which are most likely mucoid cells. A fair number of micro-organisms are present. I will repeat again for the sake of clearness that mucus is represented microscopically by a stringy medium studded all over mostly with round cells—mucoid cells—and also some pavement epithelia. It is rather of a dark yellowish color, when specimen is stained with iodin solution and rather dark when unstained. A strong iodin solution stains it blue and may then be mistaken for starch.

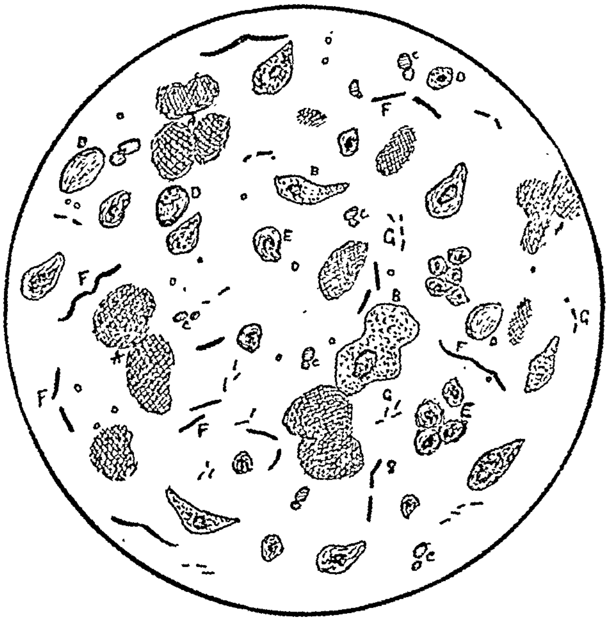

Fig 8.—Carcinoma ventriculi. Test breakfast; A, starch; B, epithelial cells; C, yeast cells; D, fat globules; E, round and mucoid cells; F, Boas-Oppler bacilli, single and in chains; G, micro-organisms. Leitz No. 7 objective; Ocular No. 2.

Carcinoma of the Stomach.—The contents are thick; very little gastric juice as a rule. At times there is some juice, but the bread in it looks just as if it were soaked in it. Large undigested particles of food, chiefly meat, if the patient has no aversion to it, are found in the stomach contents. Very often we get coffee-grounds with it, when the carcinoma ulcerates and small hemorrhages take place. The contents look at times not unlike feces, coming out through the stomach-tube like molds in large quantities. An appearance like this latter is pathognomonic of cancer. It is met in those cases in which the carcinoma invades both the pylorus and the stomach wall. Carcinoma contents look very much at times like those of chronic gastritis, but in the latter there is a good deal of mucus, while in carcinoma mucus is rather uncommon, although it is encountered in some cases, since the cancer often induces a secondary gastritic process in the part of the stomach not invaded by the cancer. The odor in cancer contents is offensive.

Microscopic Appearance: The starches are very well digested and they are, therefore, stained but faintly with the iodin solution. Fat globules are usually present, since in most carcinomas, even in those that are not situated at the pylorus, the motility is below par, and some stagnation is present, and, therefore, fat globules are the rule even with an Ewald test breakfast. We seldom find muscle fibers, since these patients develop an aversion to meat. Should we give the patient some meat with the meal, we will find the muscle fibers very poorly digested, as the absence of the pepsin and hydrochloric acid leave the muscle fibers unaffected. Their striæ are prominent and intact. Large numbers of cellular elements, pavement, small round, large round and cuboidal epithelia, float around in great abundance more than in any other kind of stomach contents. They are, however, always single cells or a few together. Unfortunately, I never met large conglomerations of them, particles of tissue that should enable us to identify them as being fragments of a cancer. There is an absence of sarcinæ in cancer, even in cases in which the cancer invades the pylorus. The characteristic microscopic feature of cancer of the stomach, however, is the Boas-Oppler bacillus. This is a rod-shaped bacillus, non-motile, which forms long chains. It does not need any staining and can be easily identified even with a low power. There is no need for an oil immersion; a 6 or 7 objective (Leitz) brings out all its features. The Boas bacillus is an almost constant inhabitant of the cancer stomach. Most cases of cancer of the stomach show it. This is conceded by most authors. It is seen in larger numbers in washings of a jejune stomach than in food contents. It seems as if that bacillus were taking shelter in the folds of the stomach wall. It is of diagnostic value only when present in large numbers. A few isolated bacilli have no diagnostic significance. There has been considerable controversy among stomach specialists as to the origin of the Boas bacilli, some considering them as the result, while others consider them as the cause of lactic acid. While it is a well-known fact that the Boas-Oppler bacilli can produce lactic acid, it is equally well known that various micro-organisms are capable of producing lactic acid under favorable circumstances, i. e., when the bacilli are given plenty of time to act and when there is an absence of hydrochloric acid. Cancer of the stomach with its poor motility and its anacidity is admirably adapted to these purposes. I wish, however, to correct the prevailing erroneous idea that Boas bacilli and lactic acid always go together. I can state positively that I have met cases in which Boas-Oppler bacilli were present and no lactic acid and *vice versa*. I have seen several clear-cut chronic gastritic cases with presence of lactic acid, but no Boas bacilli were present. I took special care to ascertain that the patient had a lactic-acid-free test meal and did not ingest the lactic acid.

Other micro-organisms are also present in large numbers. The stomach teems with them in cases of carcinoma more so than in any other pathologic condition of the stomach.

Microscopic Appearance of Stomach Washings: The great abundance of cellular elements, pavement, round, cuboidal and cylindrical, the Boas-Oppler bacilli in large numbers and a very rich microscopic flora make almost a diagnostic microscopic picture.

Gastric Erosions.—In siphoning stomach contents or in doing lavage we sometimes find bits of gastric mucosa of variable size. They are red in color and may be mistaken for bits of fresh meat or corned beef, the differentiation of which is often made possible only through microscopic examination. Dr. Max Einhorn[3] has described conditions in which these bits of mucosa have been especially prevalent, as a separate disease, by the name of gastric erosions. These bits of mucosa cannot be caused by trauma, such as could be inflicted by the stomach-tube, since their finding is not accompanied by bleeding. While it is of great interest to make sections of them for microscopic studies, most writers agree that these bits of mucosa cannot serve as true representatives or samples of the general condition of the gastric mucosa.

Nervous Dyspepsia and Other Gastric Neuroses.—These present nothing distinctive in the appearance of their stomach contents and give the same picture, both in gross and microscopically, as normal stomach contents. There is no better guide in differentiating a neurosis of the stomach from an organic lesion (except ulcer) than by the gross and microscopic examination of the stomach contents. A normal macroscopic and microscopic picture of stomach contents with a stomach history, provided we can rule out diseases of other organs, means a gastric neurosis.

In conclusion, I wish to thank my brother, Mr. Samuel Weinstein, for his painstaking execution of the drawings.

61 East One Hundred and Seventh Street.

THE WORK OF A COÖPERATIVE HYDROTHERAPEUTIC ESTABLISHMENT *

JOSEPH H. PRATT, M.D.
Instructor in the Theory and Practice of Physic, Harvard University; Physician to Out-Patients, Massachusetts General Hospital
BOSTON

In 1903 Dr. James J. Putnam and a number of other Boston physicians established a cooperative hydrotherapeutic institution under the name of the Medical Baths. Rooms were secured and equipped on the top floor of a modern office building conveniently located near the residential part of the city. The object of the enterprise was to furnish facilities for hydrotherapeutic treatments, especially those that require elaborate apparatus and skilled operators, so that all physicians in Boston and vicinity might avail themselves of these approved forms of treatment. At that time there was not a hydrotherapeutic douche apparatus or an electric light bath in the city, and the physicians who wished to have a patient given a wet-sheet rub or a carbon dioxid bath did not know where to find a man or woman familiar with the proper hydrotherapeutic technic.

At a meeting of physicians called by Dr. Putnam in October, 1903, it was decided that there was enough interest in hydrotherapy among physicians to make the plan of maintaining a [illegible] institution feasible and desirable. The institution when opened consisted of a large reception-room, five dressing-rooms, a large treatment-room, a douche-room, two toilet-rooms and two storerooms. The services of a professional decorator were secured in arranging tasteful and appropriate furnishings. Every aid to cleanliness and cheerfulness was introduced and the rooms were lighted from above as well as from the sides. In the large treatment-rooms yellow-stained and leaded glass was used in the windows which form nearly the entire side of the room. This shut out a dreary scene made up of chimney tops and railroad tracks and gave the effect of diffuse sunlight; the suggestion of warmth was produced even on a dark winter's day. The expense of fitting up the rooms amounted to about $2,000; and this was paid by gifts and loans from friends interested in the enterprise. Pledges amounting to $2,000 were secured to cover a possible deficit during the first year. To this guarantee fund many physicians subscribed. A complete douche apparatus and two hot-air cabinets were furnished by Dr. Putnam. The management of the establishment was in the hands of a committee composed of Dr. J. J. Putnam, E. G. Cutler and R. W. Lovett. I was made the medical director.

---

[3] Einhorn, Max: Med. Rec., June 23, 1894.

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In his first annual report Dr. Putnam said:

> With the increasing experience of our operators, there is no malady for which patients now take long journeys to distant water-cure establishments that cannot here be adequately treated. It is, moreover, unique in being a physicians' establishment, founded to promote the needs of the profession and their patients as well as the education of students and nurses as far as that is practicable, and conducted in such a manner that physicians can send their patients without fear that their relations to them will be anything but strengthened.

Nearly five years have passed since the above was written and time has demonstrated that the institution fills a real need. Furthermore, it has won the confidence of the medical community. Recently a circular letter was sent to 2,000 physicians in and about Boston asking them if they approved of our establishment and inviting criticism. Ninety-eight per cent. of those who replied wrote in commendation of the work.

PRESENT ORGANIZATION

In December, 1908, the enterprise was incorporated under the name of the "Institution for Physical Therapeutics." This placed it on a proper financial basis. If the institution had failed previously, or if suit had been brought against it, the committee of three physicians would have been liable for any amount. The capital stock of $10,000 is divided into four hundred non-assessable shares of $25 each. A circular letter was sent to every physician in eastern Massachusetts setting forth the purposes of the organization and inviting subscriptions for stock. The corporation is governed by a board of nineteen directors, consisting of seventeen physicians, one lawyer and one financier. The details of management are in the hands of an executive committee composed of five directors, including the president, Dr. J. J. Putnam. There is a restriction on the transfer of stock which will prevent it from passing out of the hands of physicians and will enable the corporation to purchase stock of any who wish to sell. It is the purpose of the directors to use any profits that may be realized to making improvements and in advancing physical therapy rather than in paying dividends on the stock.

Last year three more rooms were added, so that now there are accommodations for eight patients. This permits a rest in bed for several hours, if that is desirable, as it often is in connection with sedative procedures. With the smaller number of rooms it was sometimes necessary to cut short the period of rest, as the room was needed for another patient. The superintendence of the establishment is in the hands of a matron, who arranges the appointments for treatments, receives the patients, assigns the rooms and collects the fees. If the operators are negligent or if complaints are made by the patients she reports at once to the medical director.

The forenoons are given up to women patients, the afternoons to men. All treatments are by appointment. There are two chief attendants, a man and a woman, and each has an assistant. All four of the attendants were trained in an excellent school of medical gymnastics and are skilled in mechanotherapy as well as in hydrotherapy.

No patient is treated unless he brings a prescription from a physician. A detailed record is kept by the operator of each treatment. Accompanying is the record in a case of slight cardiac insufficiency for which carbon dioxid baths were prescribed.

The chief attendant reports to the director daily the name of each new patient and the immediate effect of the treatment. The majority of treatments come under the head of stimulating or tonic procedures. These consist of a cold application to the warmed skin. If the cold procedure prescribed is not too intense for the individual's reactive powers a good reaction always results provided the treatment is properly given. If a good reaction is obtained, then the effect, so far as the attendant is concerned, is satisfactory. The following day the physician is informed that his patient has had the first treatment and a note is added in regard to the reaction. Last year when a physician referred a patient to the institution for the first time a letter like the following was sent to the doctor:

> Our chief attendant reports that your patient, ————, took his first treatment yesterday at the Medical Baths and a good reaction was obtained.
>
> We are urging all physicians who are sending patients to the baths to familiarize themselves with the details of modern

hydrotherapeutic technic. No one can doubt that hydrotherapy, the most important of all the forms of physical therapy, will play as important a part in the therapeutics of the future in America as it does to-day in Germany.

If physicians accompany their patients for the first few treatments they soon gain a working knowledge of hydrotherapy, and the effect of the doctor's presence on the patient as well as on the attendant is beneficial. When patients begin a course of hydrotherapeutic treatments they are frequently apprehensive and distrustful. Those physicians have obtained the best results who have been present at one of the first treatments. They have been able to arrange or to discuss with the attendant the details of the hydrotherapeutic procedure and to observe its immediate effect. If this plan is followed it will be found that the patients take up the course of treatments with more confidence and earnestness. This is particularly true in the case of neurasthenic patients in whom the psychic effect of the treatments is especially pronounced.

EQUIPMENT

The chief apparatus is as follows:

1. Electric light cabinet. This is an octagonal box lined with plate-glass mirrors and lighted with eight rows of six incandescent lights.
2. Two cabinets for hot-air and vapor baths.
3. Incandescent electric light bath for treating single parts of the body.
4. Arc-light with reflector for local treatments.
5. Local hot-air bath.
6. Douche-table with which a large tank for hot water and a pressure pump is connected. Temperature and pressure are completely under the operator's control.
7. Circular douche (needle-bath).
8. Rain douche (shower-bath).
9. Horizontal douche (spout).
   (a) Jet douche.
   (b) Fan douche.
10. Ascending or perineal douche.
11. Sitz-bath.
12. Porcelain tub used for
   (a) carbon dioxid baths.
   (b) electric baths.
   (c) half-baths.
   (d) full baths.
13. Electric cabinet (galvanic, faradic and sinusoidal).

FORMS OF TREATMENT

They can be divided into two classes, (1) the general and (2) the local. Most of the general treatments can in turn be separated into the stimulating and the sedative.

The immediate object of the stimulating or cold-water treatments of short duration is to produce a good reaction.[1] One understands by a reaction the secondary dilatation of the cutaneous vessels which follows their primary contraction produced by the stimulus of the cold water. There is an increased flow of blood through the dilated vessels, the skin reddens and there is a pleasant sensation of warmth, often accompanied by a feeling of well-being.

To promote a good reaction the skin should be warm and filled with blood before the application of the cold water. For this purpose we use chiefly electric light baths of short duration. Formerly hot-air baths were employed, but light baths are more satisfactory. In general the colder the water, the shorter its application; and the greater the force of impact on the skin, the more prompt and intense the reaction.

The mode of drying the patient and the after-treatment are important considerations in the production of a reaction. Rough towels should be used and vigorous friction applied to the body. If the individual is weak and anemic it is well after the treatment to put him to bed well rolled up in blankets and, if a reaction does not promptly develop, to place hot-water bottles at the feet and over the spine. If the patient is strong and vigorous it is advisable for him to dress without delay and take a short, brisk walk which will promote the reaction. Active measures are always better than passive, unless the patient is enfeebled. Hence, a walk after the treatment is better than massage if the condition of the patient permits.

Failure to understand the nature and significance of the reaction accounts for many mistakes in preparing hydrotherapeutic prescriptions. A measure of the reactive power of the patient can be obtained with the procedure known as the ablution with friction. This is the *Teilwaschung* of the Germans. It is the mildest general treatment, and can be employed to advantage even in the treatment of feeble, bedridden patients. The water is best applied with a wet bath mitten. One part of the body after another should be rubbed, first with cold water (50-75) and then with a rough towel. If the circulation is poor alcohol may be added to the water. The skin of the part treated should become red and warm. The intensity of the local reaction furnishes a guide to the selection of the proper tonic measure. If a good reaction is obtained with the ablution, stronger measures may be used, of which the douches have the greatest range of usefulness. A prescription that I often give is the following:

℞.

Electric light bath for	5 to 10 minutes
Circular douche at 105°	30 seconds
Circular douche at 90°	30 seconds
Jet and fan douche to entire body at 70°	20 seconds

Pressure, 10 pounds.

Repeat daily, gradually increasing pressure of jet douche and lowering terminal temperature until pressure of 20 pounds and temperature of 60° are used.

The following is a list of general stimulating treatments:[2]

1. The ablution (wet mit. friction).
2. The wet-sheet rub.
3. The half bath. Temperature, 70 to 85. Duration 1 to 5 minutes.
4. The douches:
   (a) circular douche, 60 to 70. Pressure, 8 to 15 pounds; duration, 50 to 60 minutes.
   (b) Jet and fan douche, 60 to 75. Pressure, 10 to 25 pounds.
5. The faradic electric baths. Temperature 90 to 93.
6. The carbon dioxid baths. Various strengths; temperature 85 to 92. Duration, 7 to 15 minutes.

The chief sedative treatments are as follows:

1. The wet pack.
2. The dry blanket pack.
3. The hot-air bath. Temperature, 115 to 140. Duration, 15 to 25 minutes.
4. The electric light bath. Temperature, 110 to 140. Duration, 15 to 30 minutes.
5. The neutral full bath. Temperature, 90 to 93. Duration, 10 to 45 minutes.
6. The hot full bath. Temperature, 104 to 108. Duration, 5 to 10 minutes.
7. The galvanic bath. Temperature, 90 to 93. Duration, 5 to 15 minutes.
8. The sinusoidal bath. Temperature, 90 to 93. Duration, 5 to 15 minutes.

---

[1] The cold procedures of longer duration so valuable in combating infectious fevers are not discussed in this paper.

[2] The technic of the different procedures will be found described in detail in the excellent works of Matthes, Baruch, and Kellogg on hydrotherapy.

Local treatments with heat produce hyperemia and are used chiefly to relieve pain, to lessen inflammation, and to improve the nutrition of the affected part. They are most useful in the treatment of the various joint troubles, neuralgia, neuritis and muscular affections.

1. Electric light (incandescent) bath.
2. Arc light with reflector.
3. Hot-air bath.
4. Hot-air douche.
5. Hot-water douches:
    (a) Simple hot douche.
    (b) Scotch douche.
    (c) Alternating douche.
6. Fomentations.

Of the various treatments given in the above list we use the electric-light bath, the wet mit friction, the circular and horizontal douche and the carbon dioxid bath more than all others combined. The hot-air and vapor baths are rarely employed, as their place has been taken by the electric light bath. Nearly all patients object if the hot-air bath is substituted for the light bath. The light bath of short duration usually produces the sensation of a pleasant stimulation, while a hot-air bath often gives rise to a slight feeling of oppression. Sweating occurs more quickly and at lower temperature in the light bath.

Simplicity in prescribing is well nigh as important in hydrotherapy as in pharmacotherapy. In some American sanatoriums a confusing variety of treatments are given to a single patient. This practice has all the faults of the ordinary "shotgun" prescriptions and at the end of several weeks it is impossible to decide which of the various procedures used has had a beneficial effect.

In writing prescriptions the exact temperature of the water should be stated and the exact duration of treatment. Cold water and hot water are relative terms. Tap water is commonly regarded as cold water. Yet it varies in Boston from 40 degrees in winter to 75 degrees in summer . It should be remembered that hydrotherapy is really thermotherapy, for it is the heat of the water and not the water itself that is the therapeutic agent. A full tub bath at 80 degrees, of five minutes' duration, has a tonic action, but a full tub bath of 92 degrees, of fifteen minutes' duration, has a pronounced sedative effect.

INDICATIONS OF HYDROTHERAPY

Hydrotherapeutic procedures are of value in the treatment of almost all chronic diseases. I have found them of great help in improving the general condition of patients. An increase in appetite and a better circulation of the blood in the skin and subcutaneous tissues is usually observed; and there is a beneficial action on the peripheral nervous system and increased functional activity of the skin.

The importance of hydrotherapy in anemia, in malnutrition, and in convalescence from acute diseases is not sufficiently recognized. As it can lessen pain and give a sense of physical comfort, it has a wide field of usefulness in the care of patients suffering from incurable and fatal diseases. Special emphasis should be placed on the fact that the simple physical measures can often replace the objectionable narcotics in the treatment of chronic maladies. A patient with tabes who had not had a good night's sleep for six months owing to lightning pains was able to sleep and to keep at his work an entire season with the aid of neutral and carbon dioxid baths without recourse to analgesics or narcotics.

Hydrotherapy is a most useful measure in cases of psychoneurosis that present somatic manifestations or in which the physical condition is not good. I have employed it with benefit in psychasthenia and other mental disturbances. Hydrotherapeutic measures given by skilful attendants in a well-equipped and well-conducted institution have an important psychic influence for good. This is increased by the general sense of refreshment and invigoration produced by the reaction that follows a stimulating procedure. In individuals who are not readily suggestible definite sensations of physical well-being are often necessary before there can be any improvement in the mental condition. Hope of recovery is not infrequently strengthened as a result of a good reaction, and fears and anxieties temporarily cast aside.

Cold applications exert a definite influence on the will-power, the effect of which on the psychical condition, as Brieger points out, should not be underestimated. The patient is subjected to cold stimuli, which often produce unpleasant sensations, especially at the beginning of the treatment. Sooner or later the patient realizes the beneficial action and then willingly submits to the initial feeling of discomfort. This develops increased mental stamina. Hydrotherapy should, of course, form only a part of the treatment, and other measures, such as diet, rest, isolation, exercise, work, and drugs, should be used as indicated.

The great majority of the patients sent to our institution have been affected with various forms of psychoneurosis. There have been many joint cases, not a few of which have been arthralgias of psychic origin, although most of these were mistaken for chronic rheumatism. The number of patients with arthritis, anemia, nephritis, neuralgia, neuritis and other organic diseases have been small. It is hoped that as knowledge of hydrotherapy increases among the profession it will be used more in these conditions. In Berlin during a space of less than three years 504 cases of sciatica were treated by Brieger in the hydrotherapeutic institution of the university. During the same period we treated less than half a dozen cases of sciatica in our institution, yet there was no other place in Boston where the methods employed by Brieger were available. This means that many sufferers from the disease in Boston were denied the most approved treatment for the subacute stage.

In disturbances of psychic origin the immediate effect of the treatment on the mind of the patient can never be predicted. Sometimes there is speedy improvement, but often subjective symptoms remain unchanged or are increased after the first one or two treatments and the idea gets fixed that no benefit will result. But persistence in treatment over weeks and months often leads to great improvement or even cure in this class of cases. Success depends largely on the masterfulness of the physician in charge. Dr. Baldwin has shown that remarkably good results can be obtained in time even in severe psychoneuroses if the doctor is tactful and controls the patient with a firm hand.[3]

Many cases of neurasthenia are seen in which it is difficult to determine whether a stimulating or a gentle sedative treatment is indicated. Every patient must be studied individually, and it may take some time before the proper procedure is found. No two cases are quite the same. As George Beard truly said, "If two cases are given the same treatment from beginning to end it is probable that one of them has been improperly treated." I have sometimes followed the practice of Binswanger in giving three different treatments on three successive days. After these have been repeated once or twice the treatment which seems to the patient to be most beneficial is selected. Usually one of the procedures will be condemned and one favored. In this way the support and confidence of the patient is gained.

---

[3] Baldwin: The Personal Element in Prescribing Hydrotherapy, Boston Med. and Surg. Jour., 1909, clx, 468.

The following sample outline of treatment is given as a suggestion:

First Day: Electric light bath, 5 to 10 minutes, followed by wet mit friction.

Second Day: Carbon dioxid bath (half full strength), 10 minutes.

Third Day: Wet pack, duration 45 minutes to 1 hour.

Repeat treatments in the same order on the fourth, fifth and sixth day.

From half an hour to an hour of physical and mental rest should follow each treatment, unless the patient is robust and with good reactive powers, when a brisk walk may be substituted. Often it is a good idea to combine rest and exercise by having the patient dress quickly, walk a certain distance and on reaching home rest in bed for thirty minutes to an hour. A good proportion of the neurasthenic patients wish to discontinue treatment after the first or second bath has been taken. In many neurasthenic women a feeling of exhaustion comes on a short time after the treatment and persists the remainder of the day. This is usually regarded both by physician and patient as evidence that the hydrotherapeutic procedure has been too strong, but, as this temporary exhaustion develops after the mildest treatments and as it almost invariably disappears after the second or third treatment, the sensation of weakness is undoubtedly due in the great majority of cases to the nervous strain of the visit to the institution. The surroundings are new and the appliances are strange and somewhat formidable in appearance. I have known even physicians to appear nervous and apprehensive when placed in the electric light cabinet for the first time. Recently I saw a patient in whom weakness and depression persisted until the sixth treatment. Since then she has felt refreshed and invigorated after the bath for the rest of the day. It was possible to prove beyond question in this instance that the weakness was of purely psychic origin because the patient felt as tired after a mild treatment (wet mit friction) as after a strong one (circular and horizontal douche).

For patients who cannot afford daily treatment at our institution I prescribe three treatments a week at the Medical Baths and a home treatment in the form of a neutral bath, or half bath, on the other days. It is well to have the home treatment taken at the same hour as that at the institution.

After considerable experience with carbon dioxid baths in the treatment of cardiac insufficiency I can only say that they have seemed to be decidedly beneficial in certain cases. The carbon dioxid baths raise the blood-pressure and produce in some instances a transitory reduction of cardiac dilatation. Often I have failed to note any improvement, and never when the heart muscle was markedly weakened. In the cardiac neuroses they are of undoubted value. Care must be exercised to select a bath of proper strength. Weak hearts are frequently overtaxed by strong baths. I have observed cases in which the congestion-dilatation of the heart was distinctly increased by the bath. If there is a fall in the blood-pressure after the bath (temperature 87 to 92 F.) it indicates that the heart is weak and the bath too strong. We usually begin the treatment with a bath one-fifth or three-tenths full strength.[4] The attendants take the blood-pressure before and after every carbon dioxid bath. I have found that the action of baths of different strength on the blood-pressure furnishes a useful method for determining the functional power of the heart muscle.

INFLUENCE OF THE INSTITUTION IN ADVANCING PHYSICAL THERAPEUTICS

The facilities of the Boston establishment have been utilized at different times during the past five years by about 200 physicians in the treatment of their patients.

Since the opening of this institution several Boston hospitals have installed hydrotherapeutic equipments. Several skilled attendants employed in local hospitals were trained in the technic of water treatments at our institution.

Demonstrations in hydrotherapy have been given to students of the different medical schools in this city.

Our organization, cooperating with local medical societies, has secured several addresses by prominent physicians on hydrotherapy and other forms of physical therapeutics.

Reprints of articles on hydrotherapy have been sent to over 2,000 physicians in eastern Massachusetts.

The institution has been visited by physicians from many parts of the country and establishments patterned in a measure after ours have been started in other places.

313 Beacon Street.

ABSTRACT OF DISCUSSION

Dr. John A. Lichty, Pittsburg, Pa.: Such an institution as described by Dr. Pratt is, I think, a necessary adjunct to the physician's armamentarium. If the physicians do not become active and take up this matter, the quacks will, and with great harm to the patients. All of us no doubt have had the same experience. I have in mind one patient with loss of cardiac compensation, enlarged liver, etc., who went to an ordinary masseur, or a man who called himself "professor of hydrotherapy" to have his enlarged liver reduced in size. The massage and exercises prescribed led to serious results. This I have seen frequently, and I believe we should protect ourselves against these men. Unless we establish such institutions, we will be at the mercy of these men. The difficulties mentioned I believe to be the difficulties one would expect naturally in trying to treat ambulatory patients. It is difficult to prescribe a treatment to be taken in the patient's home. If the patient will go to a hydropathic institution, he will go to the physician's office. If a woman is to take the treatment, she dresses, goes down the street, takes the treatment and then goes to a department store to do her shopping. The good that follows the carrying out of such a course, under such difficulties, is small. In Pittsburg, such an institution is about to be opened, and I think we shall get good results from it. If we could send patients to Boston and have them devote the time necessary for the treatment in Dr. Pratt's institution, I know good results will follow; I also believe that if those patients who were not much benefited at his institution in Boston, were sent to a similar institution at Pittsburg, away from their home and environment, in all probability good results would follow. These patients take the treatment much better in institutions devoted to that purpose. In this country the watering-places and institutions are not manned as in other countries. Some of the best scientific work originates in some of these establishments in Europe. Good men are there to watch their patients carefully and prescribe the treatment to be employed. There are very few institutions in this country where the patients can be so treated; what is being done in this line, however, is being appreciated. At these watering-places the patients can enjoy themselves. The treatment in this country is a business; there is no amusement, no enjoyment for the patients in the institutions we have here. It is different in the watering-places in Europe. One advantage that is coming from the establishment of these institutions is the education of helpers so that the treatment may be carried out in the patient's own home. I am sorry Dr. Babcock is not here to tell of the Nauheim treatment as he has it carried out in the patient's own home. Nauheim himself has stated that it cannot be done at home; but Dr. Babcock has proved that it can be done and with very satisfactory results when the conditions can be entirely controlled.

---

[4] Detailed directions for preparing the baths are given in Matthes' Lehrbuch der klinischen Hydrotherapie, Edition 2, Jena, 1903, and in Romberg's Lehrbuch der Krankheiten des Herzens, Stuttgart, 1906.

DR. G. C. SMITH, Boston: Dr. Pratt's work in Boston is well known throughout the New England States, and especially in Massachusetts, while in the South and West people have heard much less about it.

One or two points suggested by the paper I would like to touch on. There is a class of cases in which I have found hydrotherapy especially adapted, namely, vasomotor conditions with a neurotic etiology; also vasomotor conditions arising from a failing heart in cardiac disease, a condition so often seen in young boys and girls. These conditions are quickly relieved by hydrotherapeutic measures. Often patients who have been very little benefited by drug treatment can be satisfactorily treated by good sanitary measures, open-air life, proper diet and hydrotherapy, and show rapid improvement under such conditions. Other patients who do much better in America than abroad are the patients with broken compensation. This is my opinion after a study of the institutions abroad. The reason is that the physician knows the patient and is interested in him; he knows all the individual's idiosyncrasies. At Nauheim or other sanitaria abroad the patient is treated more largely from a cardiac standpoint which does not always work out well. I have had many patients try the Nauheim treatment, and they still continue to try it. They go abroad and spend from four to six weeks, and sometimes it is claimed that the transverse cardiac dulness has been reduced two inches in that time. That is absurd. The only way to do away with the stupendous outflow of the misinformed and misled from this country is to let the real facts be known. I know of several individuals in Boston who have been treated at Nauheim and other spas abroad who now make it a regular thing to consult the family physician in Boston and have a thorough examination before going. On their return they do the same thing. In these patients we cannot find the same diminution in the cardiac dulness as the foreign physicians claim. I am sure that hydrotherapy does help these patients. It must be remembered that many patients who have cardiac disease must be treated at home, and that this number is much greater than the number going abroad.

DR. ANDREW MACFARLANE, Albany, N. Y.: The first duty of the physician is to cure his patient, and there is no question that the true way to do this is to find out the cause of his difficulty and remove it. This, however, does not appeal to the popular mind. Consider what has been done to stop the spread of smallpox by vaccination and to prevent typhoid fever by a pure water supply; the citation of such facts, however, does not present an argument to the average popular mind that will have any marked influence. If a patient with a stiff joint consults physicians, they are likely to give him pills, solutions, powders and liniments and often without much effect. The patient then goes two or three times to an osteopath, gets as many treatments and is benefited. He then is convinced that the osteopath is a better physician than the regular practitioner. He certainly is to that extent. The great mistake is that the medical profession does not appreciate the value of physical therapy. Physicians rely too much on giving prescriptions and then sending the patient home.

In New York State there is a man who conducts a successful sanatorium; he is an ex-prize fighter. Yet his place is frequented not by the ignorant, but by the most intelligent men in the United States. I regard it as a disgrace to the entire medical profession that an ex-prize fighter should be able to do, and to do successfully, what a scientific profession is not doing. In our various efforts to secure proper legislation in New York State we had the greatest possible difficulty in proving that the so-called regular medicine was better than fake medicine.

After taking the baths at the foreign spas the patients rest. I have visited many spas in Germany and I am fairly well acquainted with the conditions existing there. The Germans have developed the scientific side of metabolism in these watering-places to an extent which we would do well to copy and imitate.

I believe that the subject that Dr. Pratt has brought up is a most valuable one, and I have no doubt but that great advances will be noted in it during the next fifteen or twenty years; but we must not expect much from it in three, four or five years. This is, however, a subject that will bear much and good fruit in time.

DR. JOSEPH H. PRATT, Boston: It is true that many patients with neurasthenia and other forms of psychoneurosis can receive better treatment in a suitable sanatorium than at home, but sanatorium treatment is frequently out of the question owing to the expense. Boston physicians have been gratified at the good results obtained by home treatment combined with systematic hydrotherapy in their local institution. In addition to the hydrotherapeutic treatment itself, the daily visit to the baths, the association with a kindly and cheerful attendant or nurse, the half-hour or hour of rest before dressing, often have a marked influence for good on both mind and body. Furthermore, the institution is an aid to the physician in his supervision of the case. If a patient is told to take a treatment at a certain hour daily in our establishment, it is an easy matter to find out whether he does so or not. A report is sent to the physicians, if requested, of the number of treatments taken by each patient and the date of each treatment.

In the management of patients with chronic organic disease, treatments at the medical baths have been of aid in encouraging the patients to persevere in following an unpleasant or exacting regimen. This is true in cases of nephritis, obesity, diabetes and heart disease. In 1905 I saw with Dr. Daniel a woman with chronic nephritis who had been ill a year. She had marked general anasarca and the day urine contained over 1 per cent. of albumin. The essential features of the treatment instituted were electric-light baths and a salt-free diet. She objected strongly to the diet, but did not abandon the plan of treatment because she felt that the light baths were beneficial. Afer three months the edema had disappeared except for a slight swelling of the legs. When last seen, three years later, the edema had not recurred and the urine contained only a slight trace of albumin. It is probable that her recovery was due more to the salt-free diet than to the light baths, yet without them she never would have continued with the diet.

It is strange that American physicians who send patients to Nauheim make so little use of artificial carbondioxid baths Krehl, Romberg and other German authorities recommend and employ in their clinics the artificial baths. There are over a dozen natural carbon-dioxid baths in Germany used in the treatment of heart disease in addition to those at Nauheim. Two patients with cardiac disease whom I referred to a leading German consultant were sent not to Nauheim, but to Homburg. What I have learned from patients returned from Nauheim bears out Dr. Smith's statement. Treatments are often given there with inadequate supervision.

There is need of a thorough and unprejudiced investigation of the effects and value of carbon-dioxid baths, and this can well be carried out in establishments like the one described.

Infant Feeding.—It has been found by those who have studied the matter that one of the most potent causes operating to prevent or diminish maternal nursing is the ignorance of the mother as to what breast-milk really means to the child. For this state of things the remedy is instruction. Mothers need to be told in no uncertain tones that if they are able to nurse their babies and do not do so, they are morally responsible for the sickness and death resulting from their neglect. Few women possessed of any maternal instinct will refuse to nurse their children if this is made clear to them.—J. M. Connolly in *Hygiene and Physical Education.*

THE HISTORY OF TWO CASES OF CONGENITAL PYLORIC SPASM

WITH REMARKS ON THE ETIOLOGY AND TREATMENT *

D. J. MILTON MILLER, M.D.
Visiting Physician to the Children's Hospital of Philadelphia
ATLANTIC CITY, N. J.

The title of this paper is a misnomer, if it conveys the impression that by "pyloric spasm" is meant the mild and common affection described by Pfaundler[1] and Cautley[2] under this name and evidently considered by them a condition quite distinct from and not likely to be confounded with congenital hypertrophic stenosis, but which, from the description of these writers, seems identical with the habitual or chronic vomiting of infancy. An unbiased study of the already voluminous literature on this subject is, to my mind, convincing that there occurs, under the term "congenital pyloric stenosis," a group of cases in which spasm of the pylorus and adjacent gastric walls is the principal, and often the only, abnormal condition present. This group comprises the majority of the cases of so-called congenital pyloric stenosis encountered in practice, and embraces those of infants who recover entirely under intelligent dietetic and other measures. It is the existence of this group which has given rise to the great confusion and division among observers as to the nature of congenital pyloric stenosis, and as to the means to be adopted for its relief—one class insisting that medical measures are sufficient for a cure, the other being equally positive that only surgical intervention can bring about permanent recovery. Notwithstanding that Heubner[3] places the incidence of pyloric spasm as but 0.5 per cent. of all children's diseases, the condition is not so very uncommon; a physician who sees many sick babies must encounter from time to time instances of the affection and although my cases might well, from the symptoms and history, be considered as mild instances of congenital pyloric stenosis, I believe that they come under the category of simple pyloric spasm, and as such they are reported.

REPORT OF CASES

CASE 1.—*History.*—G. B., a male, the first child of its parents, both of whom are and were healthy, although the mother suffered much from nausea during her pregnancy, was born after a natural labor, weighing 8 pounds. The child was suckled successfully by its mother, and weighed, at three weeks, 8¾ pounds. At this time, its illness began with occasional vomiting. This gradually increased, until it soon vomited after every meal, sometimes in small, sometimes in large quantities—now and then, more than it had swallowed at one meal. Obstinate constipation followed, the movements, which were quite natural, occurring only with enemas. Rapid loss of weight ensued, and the infant was taken from the breast. In rapid succession, condensed milk, malted milk, barley-water and egg-water, whey, and whey and cream, were tried. Of these foods, whey was the most successful, four ounces being gained in five days on it, when vomiting and loss of weight again set in.

Examination.—I saw the infant first on Oct. 2, 1908. It was then 12 weeks old, and weighed 7 pounds. It was thin and emaciated, and cried continually; the tongue was clean, and the breath sweet. That morning, it had the first spontaneous movement in five days—of good color, smooth and well digested. There was, therefore, beyond a certain amount of colic and gas, no evidence of indigestion. The abdomen was large above, and somewhat retracted below the navel. Apparently, the stomach was normal in size; but, as I have never been able to demonstrate to my own satisfaction the situation of this organ in infants, it is impossible to speak with certainty as to this point. Peristalsis could not be detected on the abdominal surface, nor could the pylorus be felt. All the other organs were normal. From this time the infant was under constant observation. The vomiting, I noted, was often explosive, often shooting out one to two feet from the baby; but at other times the stomach-contents were simply gulped up in quantities varying from a mouthful to two-thirds of a bottle; the vomiting was preceded quite frequently, with pain and contraction of the abdominal muscles. It was never especially acid, and always unaltered, whether the child was taking whey or the food on which it was afterward placed.

Treatment.—A mixture of condensed buttermilk (1 part buttermilk to 7 of water, of which 25 per cent. was lime-water), was given, two ounces every two hours, and daily lavage was instituted (salt-solution and sodium bicarbonate, one dram to a pint). After several passages of the tube, it was discovered that the stomach was never empty until two hours and three-quarters to three hours after feeding; and then, only when two ounces was given. Hence, the intervals of feeding were lengthened to three and a half hours, and the mother was instructed always to postpone the feeding half an hour, if, at or just before the meal, the child vomited. At first, the buttermilk caused diarrhea, as it often does; but this was quickly controlled with bismuth. Several examinations of the stomach-contents were made: Free hydrochloric acid was never present; the total acidity averaged 66 (about normal); pepsin-reaction was slight. Conclusive evidence of the hypertrophy, or, at least, the overaction of the pylorus and the stomach-wall, was given by the vigorous way in which the stomach would contract on the tube, after a certain amount of water had been introduced,—seizing it, and throwing its entire length into vibration; at the same time, forcibly pumping out the water, as if from a powerful syringe. After the infant had been under observation about a month, I first saw visible gastric peristalsis, and on several occasions thereafter; it was at times, feeble, at times, forcible and well marked. The progress of the child was extremely slow, and retarded by many set-backs. During these relapses, the weight would remain stationary or be lost; to be regained, as the vomiting ceased or diminished. The strength of the buttermilk and the quantity given was gradually increased; then whey was slowly added, and, finally, 20 per cent. cream; at first in small (half-dram) doses with each feeding. This process was continued until all the buttermilk had been discarded, and the baby was entirely on a cream-and-whey mixture. Further rehearsal of details would be tedious. The infant gradually recovered; the vomiting became less and less, and now, at the age of 10 months, the child weighs 22 pounds, all vomiting having ceased for a month.

This case, I believe, was one of simple spasm of the pylorus and adjoining gastric walls. It illustrates how patient, persistent and intelligent dietetic experimenting will often bring cases of this nature to a happy conclusion. More than once during its course was the question of operative interference considered; but a little more waiting always cleared up the atmosphere, so that, with the consequent improvement, the idea was dismissed.

CASE 2.—This infant, also a male, was first seen on Aug. 1, 1908, at the age of 5½ months. It then weighed 7½ pounds, having weighed 9 pounds at birth. The parents were healthy. The birth had been normal, and the baby had been vigorous for almost three weeks thereafter, when vomiting began. On account of this, it was weaned, and a modified milk-mixture was given. This not agreeing, whey, pasteurized whey, milk prepared with peptogenic milk-powder, condensed milk, and, finally, Eskay's food, were tried. Peptogenic milk seems to have been the most successful of these. Under its use, the vomiting almost ceased, and the weight, for a time, increased. When seen, the child was much wasted and very constipated, with one smooth, well-digested movement by enema daily. It was vomiting practically everything given; sometimes immediately after, sometimes long after, the three-hour feedings. The vomiting was at times projectile in character, being thrown out a foot or more from the patient. It was often very acid; and again, not at all. Of late, it had contained large quantities of mucus and gas. The upper portion of the abdomen was enlarged, and I thought that the stomach was dilated, as apparently it reached to the navel. Visible gastric peristalsis was not observed. The infant was bright and hypersensitive, starting suddenly at the slightest noise. A weak mixture of buttermilk-conserve (1 part to 6 of water, of which 33 per cent. was lime-water), three ounces every three hours and a half, together with hot epigastric applications, were advised; no medication. At first, improvement was noted; then loss. At the end of the month, however, a pound had been gained. (The buttermilk had been increased to 1 part to 4; the proportion of lime-water, 33 per cent., still being maintained). Because of the large amounts of mucus ejected, lavage with salt and bicarbonate of sodium (1 dram of each to 2 pints) was instituted. Whenever it was employed, diminution of vomiting and gain in weight resulted; but, owing to the mother's unwillingness and inability to carry it out, this procedure was used only at infrequent intervals. As the tube usually showed that the stomach was not empty until almost four hours after a feeding, the bottles were given at this interval (six times a day); and the mother was told to postpone the meals, if vomiting occurred at the time they were due. The progress of this baby was slow and painful, beset with relapses and most disappointing losses in weight. Notwithstanding this, the steps were slowly upward; after four months of treatment, the weight was 10 pounds (a gain of 3 pounds). After the buttermilk had been gradually increased to 1 part to 3, it was slowly replaced by fresh buttermilk (with 3 per cent. cane sugar and 1.5 per cent. wheat flour). Every attempt to add whey or cream to the mixture was followed by disaster. At these times only was the vomitus very acid; (usually it contained no free hydrochloric acid, with a total acidity of about 50). When fresh buttermilk was given, the lime-water was replaced by citrate of sodium (1 grain to the ounce); and that this was beneficial, was shown by an increase of vomiting on its withdrawal. To compensate for the small amount of food tolerated by the irritable pylorus, the former was strengthened by somatose and beef-juice (1 to 2 drams), with how much benefit, it is impossible to say. After the eleventh month, the vomiting diminished materially; so that now (thirteen and a half months) several days will often elapse without its occurrence, and the child weighs 14 pounds, has four teeth, and is undoubtedly on the way to complete recovery. At no time was visible gastric peristalsis observed.

The question as to the diagnosis in this case may be raised. I am sure, however, that it was one of pyloric spasm of extreme and obstinate degree, to which, from a long series of dietetic errors (five months) gastric distention and catarrh had been added. The expulsive vomiting, the early history, and the fecal movements of natural character, are sufficient to exclude simple chronic indigestion and pyloric stenosis. This case illustrates, even more than the first, how persistent and intelligent efforts at feeding will often bring success in the most obstinate instances of this affection. If there had been opportunity to have the infant under closer observation and control, it is possible that the improvement might have been more rapid.

Congenital pyloric spasm and congenital hypertrophic pyloric stenosis, though usually separable clinically, stand in close genetic relationship to each other. Hence, in considering the nature and etiology of pyloric spasm, a brief summary of its symptoms and of those of hypertrophic stenosis will not be out of place. The subjects are usually males. They are born healthy. They are commonly breast-fed. The vomiting begins from the third day to the third week, or later. It is without apparent cause, and may be very acid or entirely unaltered in character, and is often expulsive or projectile, and may exceed the amount taken. There is constipation, obstinate or partial, according to the amount of narrowing or spasm. Signs of indigestion or gastric catarrh are usually absent, at least in the early stages. Exaggerated gastric peristalsis, feeble or intense, from left to right, is almost always sooner or later observed. In the minority of the cases a mass is palpable in the pyloric region. There is rapid loss of flesh, keeping pace with the amount of vomiting. Pain (from spasm) is often present. The food remains in the stomach longer than the usual hour and a half, viz., from two to four hours.

This group of symptoms exists in greater or less degree, according to the nature of the case; whether it be one of pure or partial spasm or of true stenosis, and differs entirely from the habitual or chronic vomiting of infancy, in which there are always the evidences of indigestion, so conspicuously absent in the condition we are considering.

The conception of Koplik as to the relation and nature of the *affections* variously considered as pyloric spasm and pyloric stenosis seems reasonable and probably correct, namely: that in some of these cases there is simply pyloric spasm alone; that in others there is added to this some hypertrophy of the circular fibers, causing a more or less distinct narrowing of the orifice of the pylorus, but not sufficient materially to narrow its lumen, and permitting of the free passage of food in the absence of spasm; and that in still another variety the narrowing of the pylorus is so great as practically to close the opening, so that an actual stenosis exists. This last group comprises but a minority of the cases and includes those of patients relieved by operation alone.

That there may be a distinct anatomic change in the pylorus, and yet recovery ensue, although the pathologic condition remains, is shown by the case of Batten[4]: this patient exhibited the ordinary symptoms of hypertrophic stenosis and gradually recovered; but, at death, long after, was found to have the usual muscular hypertrophy of the pylorus. I think that the weight of evidence goes to show that in all cases spasm is a prominent and ever-present symptom, and is the cause of the symptoms observed during life; and, as in Batten's case, may and does subside, and yet the hyperplasia of the circular fibers persist. It would seem, also, from the purely clinical standpoint, that a simple spasm of the pylorus may exist without apparent anatomic change; yet it appears more reasonable to assume that in all cases there is some pathologic alteration in the structure of the pylorus, although very slight, which, under certain conditions—the swallowing of liquor amnii,[5] inappropriate food (whether from the breast or artificial), hyperchlorhydria, etc.—causes incoordination of the musculature of the pylorus and adjoining gastric walls, resulting, at last, in spasm. In a word, in cases such as I have reported as instances of simple pyloric spasm, there is underlying, as the primary cause of the spasm, a congenital defect of the circular muscle fibers at the pylorus, or of the nerves innervating them.

The relation, therefore, of the cases clinically recognized as pyloric spasm to those in which a true hyper-

THE HISTORY OF TWO CASES OF CONGENITAL PYLORIC SPASM

WITH REMARKS ON THE ETIOLOGY AND TREATMENT *

D. J. MILTON MILLER, M.D.
Visiting Physician to the Children's Hospital of Philadelphia
ATLANTIC CITY, N. J.

The title of this paper is a misnomer, if it conveys the impression that by "pyloric spasm" is meant the mild and common affection described by Pfaundler[1] and Cautley[2] under this name and evidently considered by them a condition quite distinct from and not likely to be confounded with congenital hypertrophic stenosis, but which, from the description of these writers, seems identical with the habitual or chronic vomiting of infancy. An unbiased study of the already voluminous literature on this subject is, to my mind, convincing that there occurs, under the term "congenital pyloric stenosis," a group of cases in which spasm of the pylorus and adjacent gastric walls is the principal, and often the only, abnormal condition present. This group comprises the majority of the cases of so-called congenital pyloric stenosis encountered in practice, and embraces those of infants who recover entirely under intelligent dietetic and other measures. It is the existence of this group which has given rise to the great confusion and division among observers as to the nature of congenital pyloric stenosis, and as to the means to be adopted for its relief—one class insisting that medical measures are sufficient for a cure, the other being equally positive that only surgical intervention can bring about permanent recovery. Notwithstanding that Heubner[3] places the incidence of pyloric spasm as but 0.5 per cent. of all children's diseases, the condition is not so very uncommon; a physician who sees many sick babies must encounter from time to time instances of the affection and although my cases might well, from the symptoms and history, be considered as mild instances of congenital pyloric stenosis, I believe that they come under the category of simple pyloric spasm, and as such they are reported.

REPORT OF CASES

CASE 1.—*History.*—G. B., a male, the first child of its parents, both of whom are and were healthy, although the mother suffered much from nausea during her pregnancy, was born after a natural labor, weighing 8 pounds. The child was suckled successfully by its mother, and weighed, at three weeks, 8¾ pounds. At this time, its illness began with occasional vomiting. This gradually increased, until it soon vomited after every meal, sometimes in small, sometimes in large quantities—now and then, more than it had swallowed at one meal. Obstinate constipation followed, the movements, which were quite natural, occurring only with enemas. Rapid loss of weight ensued, and the infant was taken from the breast. In rapid succession, condensed milk, malted milk, barley-water and egg-water, whey, and whey and cream, were tried. Of these foods, whey was the most successful, four ounces being gained in five days on it, when vomiting and loss of weight again set in.

Examination.—I saw the infant first on Oct. 2, 1908. It was then 12 weeks old, and weighed 7 pounds. It was thin and emaciated, and cried continually; the tongue was clean, and the breath sweet. That morning, it had the first spontaneous movement in five days—of good color, smooth and well digested. There was, therefore, beyond a certain amount of colic and gas, no evidence of indigestion. The abdomen was large above, and somewhat retracted below the navel. Apparently, the stomach was normal in size; but, as I have never been able to demonstrate to my own satisfaction the situation of this organ in infants, it is impossible to speak with certainty as to this point. Peristalsis could not be detected on the abdominal surface, nor could the pylorus be felt. All the other organs were normal. From this time the infant was under constant observation. The vomiting, I noted, was often explosive, often shooting out one to two feet from the baby; but at other times the stomach-contents were simply gulped up in quantities varying from a mouthful to two-thirds of a bottle; the vomiting was preceded quite frequently, with pain and contraction of the abdominal muscles. It was never especially acid, and always unaltered, whether the child was taking whey or the food on which it was afterward placed.

Treatment.—A mixture of condensed buttermilk (1 part buttermilk to 7 of water, of which 25 per cent. was lime-water), was given, two ounces every two hours, and daily lavage was instituted (salt-solution and sodium bicarbonate, one dram to a pint). After several passages of the tube, it was discovered that the stomach was never empty until two hours and three-quarters to three hours after feeding; and then, only when two ounces was given. Hence, the intervals of feeding were lengthened to three and a half hours, and the mother was instructed always to postpone the feeding half an hour, if, at or just before the meal, the child vomited. At first, the buttermilk caused diarrhea, as it often does; but this was quickly controlled with bismuth. Several examinations of the stomach-contents were made: Free hydrochloric acid was never present; the total acidity averaged 66 (about normal); pepsin-reaction was slight. Conclusive evidence of the hypertrophy, or, at least, the overaction of the pylorus and the stomach-wall, was given by the vigorous way in which the stomach would contract on the tube, after a certain amount of water had been introduced,—seizing it, and throwing its entire length into vibration; at the same time, forcibly pumping out the water, as if from a powerful syringe. After the infant had been under observation about a month, I first saw visible gastric peristalsis, and on several occasions thereafter; it was at times, feeble, at times, forcible and well marked. The progress of the child was extremely slow, and retarded by many set-backs. During these relapses, the weight would remain stationary or be lost; to be regained, as the vomiting ceased or diminished. The strength of the buttermilk and the quantity given was gradually increased; then whey was slowly added, and, finally, 20 per cent. cream; at first in small (half-dram) doses with each feeding. This process was continued until all the buttermilk had been discarded, and the baby was entirely on a cream-and-whey mixture. Further rehearsal of details would be tedious. The infant gradually recovered; the vomiting became less and less, and now, at the age of 10 months, the child weighs 22 pounds, all vomiting having ceased for a month.

This case, I believe, was one of simple spasm of the pylorus and adjoining gastric walls. It illustrates how patient, persistent and intelligent dietetic experimenting will often bring cases of this nature to a happy conclusion. More than once during its course was the question of operative interference considered; but a little more waiting always cleared up the atmosphere, so that, with the consequent improvement, the idea was dismissed.

CASE 2.—This infant, also a male, was first seen on Aug. 1, 1908, at the age of 5½ months. It then weighed 7½ pounds, having weighed 9 pounds at birth. The parents were healthy. The birth had been normal, and the baby had been vigorous for almost three weeks thereafter, when vomiting began. On account of this, it was weaned, and a modified milk-mixture was given. This not agreeing, whey, pasteurized whey, milk prepared with peptogenic milk-powder, condensed milk, and, finally, Eskay's food, were tried. Peptogenic milk seems to have been the most successful of these. Under its use, the vomiting almost ceased, and the weight, for a time, increased. When seen, the child was much wasted and very constipated, with one smooth, well-digested movement by enema daily. It was vomiting practically everything given; sometimes immediately after, sometimes long after, the three-hour feedings. The vomiting was at times projectile in character, being thrown out a foot or more from the patient. It was often very acid; and again, not at all. Of late, it had contained large quantities of mucus and gas. The upper portion of the abdomen was enlarged, and I thought that the stomach was dilated, as apparently it reached to the navel. Visible gastric peristalsis was not observed. The infant was bright and hypersensitive, starting suddenly at the slightest noise. A weak mixture of buttermilk-conserve (1 part to 6 of water, of which 33 per cent. was lime-water), three ounces every three hours and a half, together with hot epigastric applications, were advised; no medication. At first, improvement was noted; then loss. At the end of the month, however, a pound had been gained. (The buttermilk had been increased to 1 part to 4; the proportion of lime-water, 33 per cent., still being maintained). Because of the large amounts of mucus ejected, lavage with salt and bicarbonate of sodium (1 dram of each to 2 pints) was instituted. Whenever it was employed, diminution of vomiting and gain in weight resulted; but, owing to the mother's unwillingness and inability to carry it out, this procedure was used only at infrequent intervals. As the tube usually showed that the stomach was not empty until almost four hours after a feeding, the bottles were given at this interval (six times a day); and the mother was told to postpone the meals, if vomiting occurred at the time they were due. The progress of this baby was slow and painful, beset with relapses and most disappointing losses in weight. The question as to the diagnosis in this case may be raised. I am sure, however, that it was one of pyloric spasm of extreme and obstinate degree, to which, from a long series of dietetic errors (five months) gastric distention and catarrh had been added. The expulsive vomiting, the early history, and the fecal movements of natural character, are sufficient to exclude simple chronic indigestion and pyloric stenosis. This case illustrates, even more than the first, how persistent and intelligent efforts at feeding will often bring success in the most obstinate instances of this affection. If there had been opportunity to have the infant under closer observation and control, it is possible that the improvement might have been more rapid.

Congenital pyloric spasm and congenital hypertrophic pyloric stenosis, though usually separable clinically, stand in close genetic relationship to each other. Hence, in considering the nature and etiology of pyloric spasm, a brief summary of its symptoms and of those of hypertrophic stenosis will not be out of place. The subjects are usually males. They are born healthy. They are commonly breast-fed. The vomiting begins from the third day to the third week, or later. It is without apparent cause, and may be very acid or entirely unaltered in character, and is often expulsive or projectile, and may exceed the amount taken. There is constipation, obstinate or partial, according to the amount of narrowing or spasm. Signs of indigestion or gastric catarrh are usually absent, at least in the early stages. Exaggerated gastric peristalsis, feeble or intense, from left to right, is almost always sooner or later observed. In the minority of the cases a mass is palpable in the pyloric region. There is rapid loss of flesh, keeping pace with the amount of vomiting. Pain (from spasm) is often present. The food remains in the stomach longer than the usual hour and a half, viz., from two to four hours.

This group of symptoms exists in greater or less degree, according to the nature of the case; whether it be one of pure or partial spasm or of true stenosis, and differs entirely from the habitual or chronic vomiting of infancy, in which there are always the evidences of indigestion, so conspicuously absent in the condition we are considering.

The conception of Koplik as to the relation and nature of the affections variously considered as pyloric spasm and pyloric stenosis seems reasonable and probably correct, namely: that in some of these cases there is simply pyloric spasm alone; that in others there is added to this some hypertrophy of the circular fibers, causing a more or less distinct narrowing of the orifice of the pylorus, but not sufficient materially to narrow its lumen, and permitting of the free passage of food in the absence of spasm; and that in still another variety the narrowing of the pylorus is so great as practically to close the opening, so that an actual stenosis exists. This last group comprises but a minority of the cases and includes those of patients relieved by operation alone.

That there may be a distinct anatomic change in the pylorus, and yet recovery ensue, although the pathologic condition remains, is shown by the case of Batten[4]: this patient exhibited the ordinary symptoms of hypertrophic stenosis and gradually recovered; but, at death, long after, was found to have the usual muscular hypertrophy of the pylorus. I think that the weight of evidence goes to show that in all cases spasm is a prominent and ever-present symptom, and is the cause of the symptoms observed during life; and, as in Batten's case, may and does subside, and yet the hyperplasia of the circular fibers persist. It would seem, also, from the purely clinical standpoint, that a simple spasm of the pylorus may exist without apparent anatomic change; yet it appears more reasonable to assume that in all cases there is some pathologic alteration in the structure of the pylorus, although very slight, which, under certain conditions—the swallowing of liquor amnii,[5] inappropriate food (whether from the breast or artificial), hyperchlorhydria, etc.—causes incoordination of the musculature of the pylorus and adjoining gastric walls, resulting, at last, in spasm. In a word, in cases such as I have reported as instances of simple pyloric spasm, there is underlying, as the primary cause of the spasm, a congenital defect of the circular muscle fibers at the pylorus, or of the nerves innervating them.

The relation, therefore, of the cases clinically recognized as pyloric spasm to those in which a true hypertrophic stenosis exists is simply one of degree. Pfaundler's theory that all cases are due to spasm, and that the changes in the pylorus met at operation or autopsy are always secondary, is certainly not borne out by clinical and microscopic evidence.

[4] Progressive Medicine, Philadelphia, March, 1903, p. 218.

[5] Thompson, J.: The Clinical Examination and Treatment of Sick Children, Edinburgh and London, Edition 20, 1908, p. 122.

It is not necessary to dwell at length on the diagnosis of congenital pyloric spasm. Although theoretically its differentiation from the severer hypertrophic stenosis is not difficult, it can not be denied that in practice the obstacles may be great. Usually, however, if, in a given case, a normal or fair amount of fecal matter is passed, it may be concluded that the case is one of spasm, or that no great narrowing exists; or it exists in slight degree, and the spasm relaxes sufficiently to permit food enough to pass into the duodenum to nourish the infant adequately.

TREATMENT

The treatment of pyloric spasm is almost entirely dietetic. Drugs have little or no place. Intelligent, persistent and patient dietetic experimenting, as Koplik[6] has so conclusively shown, seems to be the key-note of success. I have seen now five instances of this affection, of which only two are reported at this time, because the others were observed at a period when the condition was not generally recognized—at least, not fully recognized by me. Most of them passed out of my hands; but I know that all the patients ultimately recovered, some of them, without any particular management. Hence, I conclude that the prognosis is good, if the case is largely one of spasm, as so many of them are.

In the feeding of these infants, it is generally taught that the quantity should be small and the intervals short; but, as it seems unreasonable to put food into an organ that has not rid itself of the last meal, I believe a better rule is to feed only when the stomach is known to be empty. This can be discovered by the passage of the tube; or, in lieu of this, by observing the latest period at which vomiting occurs after a meal, and by always postponing the feeding if vomiting takes place just before or at a time when it is due. The amount to be given is that which observation of the case teaches us will not be rejected in any great quantity. In this way, as the irritability of the stomach is gradually overcome, it will be found that larger and larger quantities will be retained. Theoretically, the infant will not gain flesh on the small amounts (only 16 to 20 ounces often) introduced by this or other methods, but practically I have found that it does, because, especially in severe cases, not half or one-third this quantity has been retained.

Breast-milk, given according to the method described, is the ideal food for these infants. If the milk of one wet-nurse does not agree, another should be tried; and, as the fat is generally not well tolerated, in many cases it may be found advisable to remove this by centrifugation. In artificial feeding, a food which is free from curds and irritating properties, and which will form no coagulum in the stomach, should be selected; such a food is whey, to which completely peptonized fat-free milk, and later cream, may be cautiously added. Buttermilk, notwithstanding the hyperacidity often present in these cases, is valuable on account of its low fat-content and the digestibility of its casein, and has been found effective in many. In my cases, a buttermilk conserve was at first employed, because of its easy preparation, and because it had proved to be a successful temporary food in other cases of difficult feeding. It was slowly replaced, in one case, by whey and cream; in the other, by fresh buttermilk. I always gave it well alkalinized (25 to 33 per cent. of lime-water).[7] In breast-fed infants lime-water may be given before, during and after the feeding, either from a spoon or by means of a medicine dropper, introduced between the nipple and lips. This (an alkali) is, I believe, a valuable addition to the dietary of these cases, whether the milk be fresh or acid. The excessive acidity, so often present, is thereby neutralized, the casein rendered more soluble and its coagulation retarded; and, as we know that relaxation of the pylorus is accomplished through the agency of the alkaline juices of the duodenum, it is not unreasonable to assume that alkaline stomach-contents might have a similar action. Citrate of sodium (1 to 2 grains to each ounce of milk, whey or buttermilk) has been recommended. It has the advantage of smallness of bulk, thereby conserving the nutritive value of the mixture given. In my second case, it was substituted for lime-water, when condensed buttermilk was replaced by fresh. That it had value was shown by the increased emesis whenever it was withdrawn. As a rule, fats of all kinds, whether in the form of cream or of olive oil or cod-liver oil, should be avoided. In my cases, they always provoked disturbance.

Stomach-washing is highly recommended by Sutherland,[8] Cautley, Pfaundler and other authors, and condemned by others. In my hands, it has proved a most valuable resource. So successful may it be in allaying the vomiting and spasm that Cautley warns against wrong conclusions which may be drawn therefrom, as to the nature or gravity of a case—whether it be one of true spasm or of organic stenosis. Lavage should be practiced daily, at first; and, later, whenever there is a return or an increase of the vomiting, or when food remains in the stomach from one feeding to another.

I believe that it also has some value as a diagnostic measure. When much spasm is present, the tube is seized and thrown into vibrations by the hypertrophied and irritable stomach, and the water pumped out much more vigorously than under normal conditions. Usually, simple saline water is sufficient; but if there is much mucus, sodium bicarbonate may be added (1 dram to a pint).

Warm applications and poultices, hot salt-bags or water-bags, and Japanese pocket-warmers, applied to the epigastrium at meal time, and for half an hour thereafter, have been advocated, and gave in my cases considerable comfort.

Drugs to overcome the irritability of the pylorus and adjoining gastric walls occupy, in this affection, a very secondary position. Opium has been recommended; but atropin, chloral, and the bromids would appear to be less objectionable, and more likely to afford relief.

Finally, in the treatment of pyloric spasm, we should never despair, remembering, if we are familiar with the history of the affection, that the most hopeless patients may recover entirely under our observation, if we are able to retain them long enough; and that, as in severe and pronounced cases the diagnosis from true organic stenosis is difficult and often impossible, the question of surgical intervention may have to be considered, yet operative measures should always be postponed so long as the infant is not actually and continuously losing weight.

ABSTRACT OF DISCUSSION

Dr. H. M. McClanahan, Omaha: A case I saw began on the third day of life, the child dying on the twenty-ninth day. Postmortem revealed a stenosis; the lumen of the pyloric orifice would barely admit a fine probe. The patient was very weak and gradually lost weight. I was unable to palpate any tumor. The increase in growth was at the expense of the lumen and not at the expense of the size. Now, is there any way by which we can say that one case is a case of pure spasm and another has an element of true stenosis involved? At the postmortem I regretted that surgical intervention had not been resorted to. In another case, in view of this experience, it seemed to me at the time that surgical interference would be justified, but the patient went on to recovery. The peristaltic wave was so distinct that the nurse could see it. The absence of the peristaltic wave might be evidence of the spastic condition.

Dr. D. J. M. Miller, Atlantic City: These infants are always hypersensitive. They start readily, are easily frightened, and should be kept as quiet as possible. For this reason stomach washing is inadvisable in many cases; and the same applies to rectal feedings. My object in presenting this paper was to show that spasm is a predominant symptom in most of the cases and that operation should always be postponed to the latest moment, for many of these infants will improve under patient and careful dietetic treatment. My second case illustrates this, though still much below weight and though the way was long the child is now practically well. Still I believe that in many cases an operation would do no harm and might be beneficial, although not absolutely necessary.

AN INVESTIGATION INTO THE CONDITIONS SURROUNDING THE CHILD IN SCHOOL *

J. W. VAN DERSLICE, M. D.,
OAK PARK, ILL.

At the meeting of the American Medical Association of 1907, following a paper on the "School Child," by W C. Hollopeter, it was suggested by A. C. Cotton that there be an investigation of school conditions undertaken by the Section on Diseases of Children. As a result a committee was appointed to investigate the present status of the school child; I was appointed for the middle west.

The intention was to cover the entire country, and the division of territory was made north and south. Early in the investigation it was learned that this division was an impractical one, as the school conditions in localities where there are separate schools for the negro were at such a variance from the average that statistics gathered in these localities were discarded and the investigation limited to cities of 25,000 population and upward in the north central states. The data used in this paper were gathered in thirty-four cities, from 904 schools selected at random, representing 369,290 pupils.

The methods used in the investigation were: first, the use of school statistics published by the various educational boards; second, correspondence with school superintendents, principals, teachers, and school inspectors; third, personal investigation.

The report of the U. S. Commissioner of Education for the year 1907 states that there were 16,829,386 pupils in the common schools; 848,191 pupils in the high or secondary schools at a total cost of $330,680,801, or a cost of $3.90 per capita of population, or a cost per pupil of $41.60 per annum.

In twenty-two of the cities under investigation the pupils were divided in the several grades as follows: first grade 87,783, second grade 61,369, third grade 57,703, fourth grade 54,220, fifth grade 50,489, sixth grade, 41,904, seventh grade 35,223, eighth grade 24,998, first year high school 13,858, second year 9,087, third year 5,572, fourth year 3,699.

The average ages taken at the beginning of the school year were first grade, 6 years 4.5 months; second grade, 7 years 10.5 months; third grade, 9 years 2.6 months; fourth grade, 10 years 4.1 months; fifth grade, 11 years 6.3 months; sixth grade, 12 years 4.3 months; seventh grade, 13 years 4 months; eighth grade, 14 years 1 month.

The variation in the ages between the various grades is not to be taken as indicating the average time spent in the grade, as the factors of non-promotion and the dropping out of the over-age child must be taken into consideration. In the primary grades the non-promotion of a large proportion of the pupils, together with the fact that but few pupils withdraw, causes the lengthened average interval, while in the grammar grades non-promotion is one of the chief causes of the withdrawal of the school child; so with non-promotion and the dropping out of the over-age child the apparent average interval spent in the grade diminishes.

The relation of over-age and non-promotion to the dropping out of the school child is shown in the accompanying table which gives the normal age per grade as used in the calculations of this article, the number and percentage of entire class of normal age pupils, the number and percentage of entire class of pupils over age, the number and percentage of class of pupils under age, with the percentage of promotions in the various grades.

TABLE SHOWING AGES AND PROMOTIONS BY GRADES

Grade.	Normal Age; Years.	Number of Pupils. Normal Age	Percentage of Pupils. Normal Age	Number of Pupils. Over Age	Percentage of Pupils. Over Age	Number of Pupils. Under Age	Percentage of Pupils. Under Age	Percentage of Promotions.
1.	6-7	65,001	88	8,863	12			68
2.	7-8	40,073	71	11,473	20.5	4,910	8.5	82.3
3.	8-9	32,252	61.6	14,346	27.4	5,759	11	85.4
4.	9-10	28,090	59	14,759	31	4,761	10	84.8
5.	10-11	25,153	60.5	12,514	30.1	3,908	9.4	82.5
6.	11-12	19,863	60.7	8,210	25.7	4,450	13.6	83.2
7.	12-13	19,988	64	5,496	22	3,407	14	84
8.	13-14	11,238	61.8	2,880	15.7	4.128	22	88

A uniform series of questions was sent to each of the principals of the 904 schools and a second series to some ten thousand teachers in these schools. The questions and such answers as can be summarized are here given, reduced to percentages for the more ready comparison when possible.

PRINCIPALS' SERIES

How many of your pupils are compelled to leave school each year because of ill health? (This includes only cases of general ill health, excluding all acute and contagious diseases and temporary illnesses). Twenty-one per cent. of the principals answered that none of their pupils were compelled to leave on account of ill health; 11 per cent. gave 1 in 500 as the proportion; 9 per cent., 1 in 250, 17 per cent., 1 in 200; 28 per cent., 1 in 100, 9 per cent., 1 in 50; 4 per cent., 1 in 33. This is an average loss due to general ill health of one in each two hundred pupils.

What is the size of your playground? Nineteen per cent had no school playground; 10 per cent. had less than a square yard per pupil; 7 per cent. had between 10 and 15 square feet per pupil; 15 per cent. had between 15 and 25 square feet per pupil; 6 per cent. had between 25 and 50 square feet per pupil; 18 per cent. had between 50 and 100 square feet per pupil; 25 per cent. had over 100 square feet per pupil.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City June, 1909.

Have you a good system of ventilation—any method insuring fresh air constantly? Twenty-two per cent. answered in the negative; 78 per cent. in the affirmative.

What method of ventilation is used? The answers varied greatly as to the system in use and the major portion of systems mentioned can not be considered adequate. The ventilation of the schoolroom is of such importance that it would seem advisable that this body take some cognizance of the methods of schoolrom ventilation which meet its approval.

Have you a sanitary drinking fountain? This was answered in the affirmative by 27 per cent.; in the negative by 73 per cent.

Do you use individual cups? This was answered in the affirmative by two principals.

Are the school toilets in good condition? This was answered "yes" in 81 per cent. and "no" in 19 per cent., but these answers do not coincide with the result of personal investigation, as in the schools visited the toilet rooms were usually found to be dark and ill ventilated.

The Care of the Rooms.—The rooms were swept daily in 80 per cent. of the schools, tri-weekly in 19 per cent. and bi-weekly in 1 per cent. The rooms were scrubbed once in two weeks in 24 per cent. of the schools, once a month in 21 per cent., once in two months in 3 per cent., three times a year in 37 per cent., twice a year in 11 per cent. and annually in 4 per cent. The school desks were washed twice a month in 7 per cent., monthly in 15 per cent., once in two months in 5 per cent., three times a year in 29 per cent., twice a year in 16 per cent. and annually in 28 per cent. The walls were washed or calcimined each year in 7 per cent., every two years in 19 per cent., every three years in 10 per cent., every four years in 12 per cent., every five years in 14 per cent., every six years in 14 per cent., every seven years in 2 per cent., every eight years in 8 per cent., every ten years in 8 per cent., every fifteen years in 1 per cent., every twenty years in 1 per cent. and never in 4 per cent. In dusting a feather duster was used in 67 per cent. and a damp cloth in 33 per cent.

Text-Books.—In 53 per cent. of the schools free text-books were used entirely. The average life of a book was given as two years in 12 per cent. of the schools, three years in 21 per cent., four years in 29 per cent., five years in 28 per cent., six years in 7 per cent., seven years in 1 per cent., eight years in 2 per cent. In no school was there any means provided for sterilizing the books; and, regardless of the condition of the previous user, the books were passed on to the next pupil without a pretext of asepsis.

TEACHERS' SERIES

Below are summarized the answers to the teachers' questions; for comparison there have been selected the answers from the first and seventh grade teachers, as time will not allow of a more detailed report.

How many pupils in your room?

Number of Pupils in Room.	Per cent. of Answers. 1st Grade.	7th Grade.
15 to 20		2
21 to 25	1	
26 to 30	2	9
31 to 35	8	23
36 to 40	29	25
41 to 45	24	13
46 to 50	18	12
51 to 55	5	2
56 to 60	7	2
61 to 70	6	2
71 to 80	..	2
81 to 90	..	2
91 to 100	..	2

What is the size of your schoolroom? The dimensions of the schoolroom have been reduced to number of square feet per pupil, as in the calculation of air space any height over thirteen feet was not believed to influence the air content of the room.

Number of Sq. Ft. Per Pupil.	Per Cent. of Answers. 1st Grade.	7th Grade.
Less than 10	4	
11 to 15	23	13
16 to 20	39	25
21 to 25	26	40
Over 25	3	22

Have you good playgrounds? Thirty-four per cent. answered "no" and 66 per cent. answered "yes."

How much time does the child have on the playground each day?

Time on Playground.	Per Cent. of Answers. 1st Grade.	7th Grade.
No outdoor recess	8	12
10 minutes	3	6
15 minutes	13	35
25 minutes	10	6
30 minutes	66	41

These are the periods the schedule calls for, but as in no school is there any covered area provided, in stormy and inclement weather the outdoor recess can not be had.

What is the longest period the child is in the schoolroom without an outdoor recess?

Longest School Period.	Per Cent. of Answers. 1st Grade.	7th Grade.
60 to 90 minutes	50	34
90 to 120 minutes	38	48
120 to 150 minutes	5	6
150 to 210 minutes	7	12

How many of your pupils must do home work to keep up with their classes? In the first grade 7 per cent. of the teachers required some home work, while in the seventh grade home work was required by 82 per cent. of the teachers.

How many of your pupils show a marked lowering of vitality or loss of vigor or a noticeable increase of nervous irritability during the school year? Forty per cent. of the teachers failed to recognize these conditions in any of the pupils, while 60 per cent. recognized it in one or more of their pupils. In the minds of the teachers the contributing causes of this condition of stress were:

Causes of Strain.	Per Cent. of Answers. 1st Grade.	7th Grade.
Too much school work required..........	78	22
Too great anxiety over grades or examinations	8	32
Too many outside cares, as the care of younger children or employment for economic purposes	14	24
Outside social distractions................	12	30
Poorly cooked or innutritious or insufficient food	42	12
Habits contracted outside the school, as cigaret-smoking, exciting companionship or bad personal habits.................	12	44

On the principals' series of questions the question, "What in your opinion are the chief causes of stress and strain in the school child?" was answered by the majority to the effect that there appeared no stress or strain in the children under their observation. Of the others answering the question each hundred principals gave the following:

Too much school work required.............	30
Too long school hours.....................	9
Poor preparation in the earlier grades.......	12
Insanitary school conditions................	9
Too many pupils in a room..................	8
Too much importance attached to examinations	5
Yearly promotions and the lockstep method...	6
Poor teachers..............................	4
Improper school seats......................	2
Outside work, as selling papers, ushering in theaters and care of young children........	14
Outside work, as music and dancing lessons...	4
Overambitious parents......................	11
Poor home environment......................	27
Children improperly clad...................	9
Children improperly fed....................	23
Insufficient sleep.........................	15
Social distractions and cheap theaters........	23
Mental insufficiency.......................	26
Lack of home discipline....................	9
Irresponsibility	6
Irregular attendance.......................	6
Physical defects...........................	9
Bad personal habits........................	15
Too much stress attached to the special studies	6

The schedules are apparently arranged with but two ideas in mind—to have the harder studies early in the session and to fit in with recesses.

Sample schedules taken at random from various school systems were found to have the same lesson periods for all the grades, no attention being paid to the physiologic fact that a child six to ten years of age can not apply the attention to a specific subject for more than fifteen minutes without undue strain. In many schools the first lesson period, which supposedly is of the hardest study, is forty minutes in length in the primary grade.

The curriculum is manifestly overcrowded. This is due to three causes: first, the domination by the colleges; second, the fact that all that has been in the curriculum at any period must remain; third, that every pupil must take all the work, regardless of personal need.

This overcrowding of the curriculum is the source of much of the criticism which is being heaped on all public school systems, and is a menace to the child in two diverse ways: first, the honest ambitious child must do more than is within the limits of his ability to do without physiologic impairment, and, second—and what is of far greater evil in its effect—is the fact that educators recognize this factor and the child himself soon learns that to do all his work well is unnecessary for promotion, and here is inoculated into him those habits of shiftlessness and irresponsibility that are the crying evil of the modern school. Through all the literature and remarks of educators one recognizes this constant wail of the inability of the school to develop the will, but all effort is placed on the intellectual capacity. The school does not educate (draw out), but rather its apparent endeavor is to pour into the child a certain definite number of facts.

There are now at work several agencies looking to the simplification of the curriculum. A committee appointed by the National Educational Association is doing a valuable work.

To sum up: It is self-evident that inefficiency exists in the working out of the educational method for the child in all departments.

To suggest improvements in the several very urgently needed reforms would take more time than is allotted for this paper. What would be of far-reaching good is the establishment of an educational health board connected with each school system, this board to be composed of physicians, with proper authority to act in safeguarding the health of the school child, and to be the final arbiter in regard to hygiene and sanitation, and to indicate the mental and physical ability of the pupil.

THE SCHOOL CHILD'S BREAKFAST*

W. C. HOLLOPETER, A.M., M.D.
Professor of Pediatrics, Medico-Chirurgical College of Philadelphia
PHILADELPHIA

To physicians deeply interested in the work of preventive, as well as curative medicine, the school child's breakfast is becoming an important factor for earnest consideration. The subject, however, is not a new one. For many years harrowing stories have reached us from over the ocean of the distressing poverty of English and French cities. Reports have come to us of thousands of children who are sent to school weak from hunger. The expensive educational system provided for the children weakened by privation and hunger in their poor homes evidently has failed to impress or benefit them to any degree. Our government, as well as the governments of several European countries, has debated and framed, year after year, various laws for the correction of the school child's condition; yet very little good in this special direction has crystallized out of the many voluminous "acts to amend an act" before the various legislative bodies. It is much more convenient for us to read, and even to reread, these many reports of the distress of the foreign child and eventually come to believe them than to investigate patiently the truth for ourselves.

The best framed legislative measures reach us from Great Britain. The British people have indulged, frequently and thoroughly, in debate on the underfed school child. It is a matter most vital to them. In April, 1905, Sir John Gorst, possessing an advanced mind, full of theories, yet lacking practical application, instituted a most appropriate comparison of the government of the people described by the Apostle as "ever learning and never able to come to the knowledge of the truth." As he states, they are always appointing royal commissions and departmental committees on social questions, but most frequently fail to carry out their many recommendations. He is found stating his case in this language: "It is true our committees found themselves unable to say whether the school child was better nourished or developed now than forty years ago, for the course of study imposed now is much more exacting than formerly. But it is a fact that the child is much better physically now, and more able to endure indoor work, so the committee felt, inasmuch as the material was better, it was desirable to demand more of the child." Another British report quoted by Sir John Gorst insists that all school children should be inspected more thoroughly, physically and mentally, and examined as to all the senses, and finally, measured and weighed semi-annually. In this way the country might learn the true facts of the child's condition—if improving or deteriorating.

While reading of our British cousins and feeling a national pride that our own country does not allow a school child thus to suffer and deteriorate, our natural complacency was given a rather rude shock by the publication of an article by that sociologic writer, Mr. Robert Hunter, implying that our country was no better than Great Britain or France, and estimating that in New York City alone 70,000 children went to school hungry. The exact number was, moreover, distressing, inasmuch as a definite number carried conviction in regard to the actual facts tabulated in so large a number. For 70,000 children to go to school hungry seemed appalling, and this occurred just during the most prosperous period of our country. The exact facts seemed more like an importation of statistics from the literature of a foreign revolutionary agitator. It did not seem to belong to our country or our investigations. The true statement made by Mr. Hunter was that 70,000 children were found in New York schools underfed, and the latter word would have expressed the real meaning of the original statement more clearly than the word hungry. Many thousands of little children go breakfastless to school at times; but the real problem is much more extensive than that, and embraces that much more numerous class of children who are chronically underfed, either because their food is insufficient in quantity, or, what is the same thing in the end, poor in quality and lacking in nutriment. Furthermore we read from John Spargo's "Bitter Cry of the Children" that from cases personally examined by himself, or by teachers acting under suggestions given by him, he found that of 12,800 children 2,950, or more than 23 per cent., either had, on the morning examined, no breakfast or a miserably inadequate breakfast of bread, crullers or crackers, with or without coffee or tea. He has also summed up the result of other investigations made in New York City, Philadelphia, Buffalo and Chicago, which show that of 40,746 children 14,121, or 34.65 per cent., had gone to school breakfastless, or with nothing more than bread with tea or coffee—certainly a very poor preparation for the day's work.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The animated discussion on the question of underfed school children which has been going on for the past four or five years, both at home and abroad, has found its way into the newspapers, chiefly through the reports of sanitary inspectors. These published statements are based on insufficient grounds. The final analysis will prove that poverty, or the want of food, is not the real cause. The child does not usually want the food in the morning. It is absurd for the excited social reformer to demand, on such slight grounds, the supplying of free meals. It is true, indeed, in every large city there are many children who go hungry to school and go because there is an actual lack of food for them. This condition is, fortunately, not common in our own country. This class of school children should be cared for by the proper charitable agencies and never by school authorities.

Viewing the question from a medical standpoint, poverty is not the cause, except in a small minority of the cases, of those school children who go hungry. All physicians, especially those dealing largely with children, note the capricious morning appetites of children who are physically below normal from any one of many causes—such as ill health, poor homes, careless personal hygiene, etc.—and this is most likely to occur with those living in city slums and crowded quarters. Any physician doing dispensary work will recognize the truth of this assertion.

For several years I have been deeply interested in the child's breakfast, and I have made careful investigation along this line to learn the actual truth. A large proportion of the children, if asked why they did not have breakfast, would quickly reply that they did not want it; or, if in the younger children, the answer would be that their mothers could not make them take any. The true answer must be sought farther back than the mere lack of food, for food is frequently abundant. The true cause is generally the personal or domiciliary hygiene of the poorer classes extending throughout several generations. Careless mother, unclean bedrooms, close and badly ventilated, late retiring hours, with heavy, unsuitable dinners, a strong disinclination for the morning bath—all tend to cause neglect of the morning meal; then the child is hurried off to school with little attention to his personal comfort in many ways, besides omitting the breakfast.

It is not among the poorer classes alone that we find the capricious morning appetite. The fault is found just as frequently among the children of the better classes. This condition prevails in a more pronounced form—the personal environment is forced and unnatural. The practice of allowing young children tea and coffee, various stimulants, the rich, late, evening meals, associated with the excitement of music and visitors until the early sleeping hours have been broken, are all active factors in producing unstable appetites. These conditions and many more could be mentioned which must be taken into account when seeking a remedy for the growing evil. Little good can be accomplished in spending public money for free meals for children who do not want to eat and can not eat in the early morning, handicapped as they are with these many difficulties.

With the object of corroborating or disproving the correctness of Robert Hunter's and John Spargo's statements of the school child's breakfast, I enlisted the services during the winter of about 100 teachers in the elementary schools and emphasized the importance of their method of questioning the young child. I insisted that the following three questions be asked: 1. Do you eat a breakfast? 2. What do you eat? 3. How long does it take you to eat? The importance of truthfulness in our answers would rest in the manner of the teacher's approach to the child. She must ask each child alone and in strict confidence; the child must not know he was about to be questioned, otherwise the answer would be prompted by his pride or his mother's suggestion—that is one reason why the answers collected by John Spargo are misleading.

The result of my winter's work is very briefly summarized as follows:

Of 2,169 children interrogated:

58 per cent. drank coffee
15 per cent. drank milk
11 per cent. drank cocoa
11 per cent. drank tea
68 per cent. ate bread
4 per cent. ate rolls
40 per cent. ate eggs
35 per cent. ate a cereal
5 per cent. ate potatoes
18 per cent. ate cakes
9 per cent. ate meat
9 per cent. ate fruit
6 per cent. ate various other foods

Only six claimed to eat no breakfast; 737 gave the time consumed in eating as follows:

2, 50 minutes
5, 45 minutes
3, 35 minutes
74, 30 minutes
27, 25 minutes
128, 20 minutes
221, 15 minutes
1, 13 minutes
2, 12 minutes
135, 10 minutes
1, 8 minutes
31, 5 minutes
3, 5 minutes
2, 2 minutes
2, 1 minute

In conclusion, while we can not draw a definite result from the analysis of so small a number of school children (2,169) as to the quantity and quality of food taken for their breakfasts, we may infer that the school child has a chance—a poor one, indeed—for a breakfast; and the reason he has so poor a one is not that he has no food, but unfortunate surroundings to prepare him for his day's work.

Our duty as physicians is to regard our professional relation not ended with the school child until definite instructions be given to the family in correcting the poor home surroundings of the child as to sleeping rooms, personal habits, as well as proper food at a given time.

It is quite evident that Mr. John Spargo's estimate of hungry school children is erroneous and misleading. This is due to the manner of his gathering his information, obtaining it collectively when every element of personal and family pride was placed on view.

1411 Spruce Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HOLLOPETER AND VAN DERSLICE

Dr. L. T. Royster, Norfolk: I am acting head of the school board in a city of 70,000 inhabitants, about 60 per cent. of the school population being in the schools. We have about 15,000 negroes in our schools, but these schools, of course, are separate.

The school authorities are the first ones to be educated in this matter. It is absolutely essential that on every educational board there be a physician; I never realized the need of that until I got on the school board myself and found that what little I could do was absolutely needed by those gentlemen, all good men but not knowing what was needed from a physical standpoint. First of all, the physical and moral development should be ahead of the intellectual. Our public school system should fit the child for the battle of life, and that is not done without a physical and moral foundation. Of first importance is sanitation. When children are educated in the proper care of their physical being, not only will they be benefited, but the next generation will receive the benefit of this education. These children will in the next generation be the legislators as well as the educators. If the Lord's prayer is taught a child at its mother's knee, that child will never forget it. It may come to feel that it does not need it, but if the occasion arises it will remember its early teaching. This is equally true of other teaching. If a child is taught that his welfare depends on physical and moral hygiene, the foundations are laid for the good of the race.

Questions come up as to whether a midday lunch is preferable or whether the child should continue his work and go home for a 3 o'clock dinner. All these questions come up from time to time, and it seems this body should go on record and let it be known that the American Medical Association stands for certain principles that are essentials in public school education. That must have some weight eventually. We must keep these facts before the public every day and every month and every year. Another thing, we are the men who influence the people in their homes. The family physician is the one who tells the mother that the child must do this, that, or the other. Mothers will do what we tell them, even if they come into conflict with the public school system. We are the missionaries. Now it seems to be a belief that anything ever put into the curriculum should never be taken out. I am a believer in two fundamental things in the teaching of children, *i. e.*, moral training and physical education. No man is educated until his moral nature is trained and from physical training you get a power of coordination and also of relaxation. Make the public feel that we are the arbiters of the situation. It is our duty to humanity to keep constantly knocking at the public door.

Dr. **Charles Douglas**, Detroit: It seems to me that this is perhaps the most important subject we could undertake in order to educate the public. Professionally we are coming in contact with the results of intense ignorance among the so-called better educated women in this country. Our work is largely to repair the damages that are the result of their ignorance. We are continually called on to correct evils among the little ones that are the result of the ignorance of the mothers who have followed the advice of some ignorant mother or grandmother. I contend that we must do all that has been said and we must go further. In every woman's college curriculum there ougnt to be a course educating our young women to know what is right and what is wrong in hygiene and dietetics, so that in after years when feeding their children they will not be dependent on some ignorant old woman for directions. We know that in the first week of a child's life damage is often done that will send the child to its grave. We should force the public to recognize that the schools are not doing their whole duty. Is it necessary to teach so much of what we all forget? Is it not better to teach young women something they will need? We should teach them what foods agree, what are the elements in food for proper nutrition and how to use the foods. If they have enough of this knowledge they won't be subjects for education by people more ignorant than themselves. Only then will we have a higher status of education than we have now.

Dr. **George F. Little**, Brooklyn: I agree that we ought to make public such action as we may take. We won't go far by merely talking this over among ourselves. This committee will report from year to year and I think they should make recommendations to be acted on by this body. I would suggest that the committee get together this afternoon and make such definite recommendations as the report may call for; that the section act on the resolutions submitted and that they be given wide publicity.

Dr. **C. G. Kerley**, New York: When I was chairman of this Section I read a paper on this subject, and a year ago I read a similar paper before the American Pediatric Society. I think we are going a little too fast. It is all right to take the matter before the public, but the first one we have to educate is the physician. The physician must realize that he has something to do besides studying pathology and therapeutics and practicing medicine. We know something that the public ought to know. We recognize this fact we come here and discuss and then we go away and the public knows just about as much through our knowledge as it did before. What physicians must recognize first is that they are, in a sense, teachers. Where does the public get its information on the subject of health and disease? From "patent-medicine" and proprietary-medicine manufacturers. How is the mother to know how to feed her child properly or how is the father to know how to eat in order to nourish his body to enable him to work, if he has never been taught? Ninety per cent. of the population eat simply to satisfy the appetite. What we must do is to teach the people how to live. Physicians must appreciate their duty to the community and then they will be able to act to a tremendous advantage for good. Instruction in vital living principles should be taught in the schools. Every large town should have a board of hygiene associated with the board of education, but to have that brought about the people must know that we have something that they need that should be brought before them.

Dr. Van Derslice tells us of the ignorance and of the neglect of children, showing that they do not have the care that the farmer gives his horses and his sheep because the child has no value in dollars and cents. The neglect of children, particularly in our larger cities, is a disgrace to our country.

Dr. **Helen C. Putnam**, Providence: The first thing to do is to educate physicians. The teaching of hygiene in recent years has grown to what may be called a specialty. Several speakers in another section discussed hygiene taught by textbooks; but our leading educators and some physicians are far ahead of that idea. Object lessons and training in habits is the most efficient method. A child can learn more hygiene in two days from a good tuberculosis school exhibit than in two years by memorizing a text-book on bad air and unclean room. The making of housewives has been mentioned. Housekeeping to-day requires scientific knowledge. Domestic science when well taught is by far the best hygiene taught in the schools, and children take it home to their mothers. Boston has exceptionally good instruction in this department, and exceptionally good health reports. School nurses are among our effective instructors. We need higher standards for medical inspection—physicians trained for it. I do not know whether one of the speakers meant to endorse the individual drinking cup in school. Theoretically he might. Experience, however, shows it to be no improvement on the common cup. Children keep it in a dirty desk, or hanging in dusty air, or wrapped in a grimy handkerchief, and lend it to their cupless friends. What morals and manners if they did not! Its details are additional burdens to teachers, parents and child. We should advocate instead the bubble fountain. School fatigue is being specially studied in laboratories. This school cachexia is largely due to lack of outdoor air. Physicians should advocate education through industrial training, outdoor games and school gardens, to introduce the open-air life. Nature study (school gardens, etc.) is the normal method of teaching the origin of new life, which it is our duty to promote. The national organization of biologists is beginning definitely the consideration of its mission in this respect, and we should cooperate in all possible ways.

Dr. **H. I. Bowditch**, Boston: As a younger member of the profession, I think we have neglected one class of students who should be thought of. When I was in college nothing was taught of our responsibility to the public. In the early years it used to be taught, but not now. We used to get an occasional lecture on ethics and the relation of the physician to the public. If the students realized their relation to the public, and what ought to be taught the public, physicians would have a better knowledge of what they have to come up against.

Dr. E. C. Hackett, Chicago: When Dr. Putnam spoke of the work of the biological society, it seemed to me a crying shame that a brother or sister profession should take up the work that physicians ought to be doing. I want to urge that the medical men and medical women in small towns are over-modest. This teaching of others will not be done unless physicians do it. I know the difficulty there is in small towns in getting accurate information on these subjects. One woman physician told me that she had had the temerity to speak in her small town on the subject of reproduction and the matter of abortion, and for speaking of such "unladylike things" she had been tabooed. We will have to come forward and show the public that the American Medical Association is behind this movement if we expect to accomplish anything.

Dr. W. C. Hollopeter, Philadelphia: My sole object in writing this paper was the attempt to go farther back than the mere want of food, and consider the general environments of the child. Much harm has been done by the sentimental writings of the sociologist in the matter of the school child's food, and especially the breakfasts, and this investigation was made to fix the facts more definitely before the profession. If I have satisfied any members of this Section that we need greater hygienic home care of the child rather than increase of food, the object of the paper will be accomplished.

Dr. J. W. Van Derslice, Oak Park, Ill.: I believe that the medical profession needs educating, but I don't know any place where physicians can go to get any sane ideas on the subject. I have worked on this committee for two years and there are very few points on which I am definitely fixed. I think this Section should take a definite stand on subjects we deliberately take up; any subject we take up must be sanely handled. I do not want anything to go out from this Section as a resolution that can be turned down as impractical. There are too many fads and hobbies; what the public wants is facts and practical ideas taken from authoritative sources.

River Pollution and the Hudson-Fulton Celebration.—A discordant note in the Hudson-Fulton glorification, says the New York *Christian Advocate*, comes from a man whose life-span almost bridges the hundred years since the Clermont made her first trip—the Hon. John Bigelow, who was born on the banks of the Hudson ninety-two years ago and has always lived beside it except when residing in Paris as consul, or minister. Mr. Bigelow opens his heart to the public in a letter to the Hudson-Fulton Commission, in which he makes the shades of the discoverer and steamboat pioneer say:

> The river you are making such an ado about discovering and navigating is not the river either of us saw. The river we know and which bears one of our names consisted of as pure and delicious water as ever descended from heaven. You have permitted it to be converted into a great sewer into which all the cesspools, barnyards, kitchens, mills and factories between New York and Troy discharge all their polluting exuviæ and rubbish, instead of sending them back on the lands whence it came and which it should enrich. In doing this you have deprived all the river counties of one of their most valuable crops. That river in our time used to swarm with shad, herring, sturgeon, striped bass, bullheads, sunfish and pan fish of many other varieties. These fish used in our times and for many years after continued to furnish at least one-third of the nourishment of all the inhabitants for ten miles back on both sides of the river from New York to Albany. If you wish to honor us for what we have done to render this magnificent waterway useful, restore it to the condition in which we left it and when it was ready to appease the hunger and thirst of millions of people. Instead of that you have not given a thought or appropriated a penny for the discharge of the first duty which our names should have prompted you to discharge.

It is perhaps too late to save the majestic Hudson from pollution, but there are still in the more recently settled parts of our country streams which nothing but immediate and vigorous action can save from similar or worse pollution. That lavish waste of natural resources which has leveled the forests of America is defiling lakes and rivers with offal which ought to be returned to the soil.

FINAL WORD ON THE STEM PESSARY FOR AMENORRHEA, DYSMENORRHEA, STERILITY, ETC. [*]

J. H. CARSTENS, M.D.
DETROIT

The many inquiries I receive from all over the country about the use of the stem pessary, with requests for reprints of previous articles on the subject,[1] have prompted me to write another article on this question. It shows that the conditions mentioned in the title are difficult to treat. Knowing that the stem pessary will relieve the patients in nearly all cases, and in order to give this method of treatment thorough publicity, I again write on the above-named subject.

AMENORRHEA

This we generally divided into two classes, the one existing in young women in whom menstruation never made its appearance, and the other in patients in whom it has been established for a shorter or greater length of time and has suddenly or gradually disappeared.

Although there are great individual variations, large statistics in different countries show that the age of the first appearance of menstruation is about the same in the white race, viz., between the fourteenth and fifteenth year. The common people understand this perfectly, and if a young girl does not menstruate at about fifteen the mother begins to worry and perhaps treats her or consults a physician. We now well know that in some cases there is no need for treatment of any kind. The patient is backward in development, is perhaps anemic, chlorotic, suffers from indigestion, or has other conditions which generally retard the growth of the pelvic organs. With our rapid development and high education, in many young girls the vital energy is used up with study, and the menstrual function is slow in making its appearance. On the establishment of ordinary rules of hygiene and appropriate treatment such patients become stronger in the course of a year or two and the menstrual function makes its appearance without trouble.

But there are other cases in which no cause for the tardy appearance can be found, but the patients have symptoms of pain and distress recurring monthly. In such cases all the long list of emmenagogues which have been handed down to us for ages are of no avail. I have tried them faithfully and never saw any benefit from them whatever. I am by no means a therapeutic nihilist. Such patients need a thorough examination of the genital organs. There is no use wasting time with all kinds of treatment. These patients must be examined under an anesthetic. If there is an imperforate hymen, atresia of the vagina, or absence or defect of any of the organs of generation, proper surgical treatment must be instituted. These abnormal conditions do not concern us to-day.

Frequently we shall find that the uterus is small, a great deal smaller than it should be; sometimes it is bent. We have a so-called infantile uterus. Sometimes the whole uterus is small, only two inches in length. At other times it is of normal length, but is very thin. In some cases the body of the uterus seems poorly developed and in other cases it is the cervix. It may be the normal length, but only as thick as a lead-pencil.

---

[*] Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at *Atlantic City*, June, 1909.

[1] Carstens, J. H.: The Stem Pessary for Amenorrhea and Dysmenorrhea, The Journal A. M. A., Dec. 29, 1906, xlvii, 2133; Infantile Uterus, etc., Am. Jour. Obst., 1903, No. 5; The Stem Pessary for Dysmenorrhea, Ann. Gynec., December, 1904.

This poorly developed condition is sometimes due to poor hygiene, improper method of living, too much mental work and too little physical exercise, resulting in a poor development of the whole body. In other cases the patient is physically well developed, but only the pelvic organs seem to be retarded. Now with this kind of cases I formerly had a great deal of trouble. I used applications, tampons, douches, and applied electricity until I got tired of it. I then began to use a small steel dilator like the Notts. By gradual dilatation two or three times a week I would develop some of these uteri to about normal size. It was painful, however, and would take months—yes, even years. Twenty-six years ago in an article I called attention to this method of treatment for amenorrhea and dysmenorrhea.

A good many years ago I read an article on the value of a string of beads introduced into the uterus for the purpose of bringing on a more profuse flow in scanty menstruation. The introduction of a foreign substance into the uterus struck me as a reasonable procedure. I then thought of the stem pessary as a possible means of relieving this condition and began to use it. I found so much benefit that I increased the indications for its use ever since.

PREMATURE ATROPHY

Then there is another class of cases in which menstruation has been regular and normal for years, but when the women are 30 or 35 years old it becomes scanty and skips and is painful. This condition you will find in women who are unmarried and take little physical exercises, but are hard workers mentally, teachers and others who hold positions of responsibility requiring a great deal of mental work. On account of non-use the uterus undergoes a premature atrophy, and on examination the uterus will be found small, like the infantile uterus above mentioned. In such cases wonderful improvement on the insertion of a stem pessary, allowing it to remain for a year or two. To this class may be added that class of superinvolution of the uterus following confinement or miscarriage. Generally the same symptoms are produced as are found in the small uterus at puberty.

AMENORRHEA IN FLESHY STERILE WOMEN

Then there is a third class of cases. Women who live high, have good digestion and are hearty eaters become fleshy; the menstruation becomes scant and sometimes disappears entirely, and the women become sterile and develop all kind of nervous symptoms. I never saw any medicine give benefit in such cases, but by the insertion of a stem pessary and by control of the method of living wonderful benefits to the symptoms and reduction of fat can be brought about.

DYSMENORRHEA

This is one of the most intractable conditions to manage. In the past many normal ovaries have been removed as a last resort in such conditions. Some women suffer pain so that they are laid up every month for a day or two or even more. If they have positions they lose them, as nobody wants the young woman who is incapacited for work every little while. Many drug habits are started on account of painful menstruation. All the remedies, local or internal, that have been used and recommended give but little relief, except some kind of narcotic; hence we can readily see how necessary it is to find some means to permanently relieve this condition.

Authors have divided dysmenorrhea into different varieties, such as obstructive, inflammatory or congestive, membranous, and ovarian. We must, first of all, see that the pelvic organs are in normal condition, and if there is partial atresia it must be remedied by forcible dilatation, etc. But this recurs in the course of a couple of months and the operation has to be repeated. To prevent the recontraction I always insert the stem pessary after forcible dilatation. In cases of membranous dysmenorrhea I thoroughly curette the uterus and swab it out with pure phenol, insert the stem, and cure the patient. The so-called congestion and inflammatory conditions usually mean diseases of the tubes or pelvic peritonitis, and so on, and these require special surgical operations. The stem pessary is not only not indicated, but is liable to light up a dormant case and cause serious consequences.

The stem pessary is indicated in those obscure cases in which we can not lay our fingers on any particular abnormal condition—the kind that used to be called neuralgic; no general defect is found, no inflammatory condition, no displacement, or anything else, simply pain during menstruation. And let me add to this that other peculiar pain occurring just between the menstrual periods which the Germans call *Mittelschmerz*, the pathology of which we do not understand. It is marvelous what beneficial results are obtained in all such cases from the stem pessary.

DISPLACEMENTS

Originally the stem pessaries were devised to keep the uterus in about the normal position. Some stem pessaries were a combination of a retroversion or anteflexion and a stem pessary, all in one piece and difficult to introduce. Others were made of zinc and copper, supposed to have an electric action. But all kinds of stem pessaries were soon discarded because they caused trouble. In the course of my experience I found that in some cases in which there was a reflection or version besides the other conditions requiring the use of the stem pessary, the latter often helped the displacement if worn long enough. As the general health of the patient improves, the ligaments regain their original tone. But the pessary must be worn at least a year or more.

STERILITY

Many of the conditions requiring the use of the stem pessary are also the cause of sterility. I had that impressed on me by some of my earlier cases. A woman, married five or more years, who had suffered from some of the above-mentioned conditions, became pregnant after removal of the stem, which she had worn for three months. This gave me another indication for the use of the stem; and, in fact, some of my patients were kind enough to call the attention of sterile patients to the fact that they had been relieved by the stem pessary and sent them to me, so that in the course of time I have had several patients who afterward became pregnant, although I never promise to relieve that condition. There is nothing lost in trying the pessary, even if it fails. Sterility is sometimes caused by poorly developed mucous membrane of the uterus and the presence of a foreign substance in the uterus, I think, will strengthen and develop the lining membrane.

CONTRAINDICATIONS

Velpeau, in 1840, was the first, I think, to urge the use of the stem pessary. Others took it up, especially Simpson. Different kinds and shapes were devised. But in those days the pessary was used for displacements principally, and, as many of the displacements were the result or coincidence with pelvic troubles, pus tubes, etc., it can now be readily seen how serious results followed their use. Dormant pelvic inflammations were relit; in fact, septic micro-organisms were sometimes introduced in the uterus and persons otherwise previously healthy soon developed pelvic trouble, so that in the course of time the profession tabooed the use of the stem pessary. It is well known that, though repeated efforts were made to re-establish their use, they soon fell into disuse again, and very justly, as they were not properly used and counter-indications not well established. Dysmenorrhea was frequently caused by pelvic inflammations of various kinds and a careless physician might use a stem pessary in such a case with disastrous results. These cases require surgical interference of entirely another kind. Versions and flexions with adhesions require different treatment. A movable displacement requires an Alexander operation or something of that kind. The stem pessary is indicated only when there is no septic or inflammatory condition in the pelvis.

Such conditions must be rigidly excluded; hence it is readily seen that the principal indication for the use of the stem is in young or unmarried women. I have had a few cases in which the stem would not be tolerated and had to be removed. In some the pessaries came half out, as the result of falls from a swing or a bicycle, and had to be removed and reinserted. Hence I want to warn the profession not to use the stem indiscriminately and again bring it into bad repute. Judiciously used, it will be a valuable aid in the treatment of these otherwise intractable cases.

TECHNIC

The introduction of the stem requires dilatation of the uterus. As this is very painful, it is necessary to give an anesthetic, although it may take only five minutes. Then the absolutely cleaning of the vagina is necessary.

I use the Chambers hard rubber stem, although others may be as good. That everything be aseptic I boil the stem with the instruments, but, as the two arms of the stem come together while boiling, I immediately, when taking them out of the hot water, separate them and dip them in cold water so that they will stay open. Generally I have the patient on the back; with vulsellum forceps I catch a lip of the uterus, pulling it down somewhat and straighten it out as much as possible. I now insert a sound to get the exact length of the uterine cavity. Then I select a pessary a little shorter (¼ or ⅓ inch) and have it ready for insertion by fixing it into the introducer. Now I dilate the uterus. As this is often small it is necessary to start with a fine-pointed dilator. I use the Notts dilator. This generally is not sufficient and I then use the Goodell-Erlanger dilator or any other kind, thoroughly opening the uterus. If there should be any endometritis or discharge from the cervix I thoroughly curette the cervix only and swab it out with pure phenol, wiping it dry. I can then insert the stem. The button at the end must be on the cervix. The stem is kept in place by a finger on the button; then the introducer is pulled out and the thing is done. If indicated, a Thomas-Hodge pessary is inserted. The physician must see that the button is in the center of the retroversion pessary. There may be a little blood lost from the dilatation; therefore, I give phenolized douches twice a day for a day or two while the patient remains in bed. Some can get up the next day, but, as a rule, I keep them in bed for forty-eight hours. Then they can get up and go about their usual vocations. They can do anything and everything, as they always did, and never know that they are wearing stem pessaries. Once in a great while in women who are very constipated the pessaries may be forced out by straining. This sometimes also occurs in cases of relaxed vaginas. In the latter the soft rubber inflated pessary will often help to retain the stem in place.

All I ask of the members of this Section is to give the stem a fair trial in those properly selected cases in which ordinary treatment has failed and let us hear the results.

620 Woodward Avenue.

ABSTRACT OF DISCUSSION

Dr. Howard A. Kelly, Baltimore: I think it would be interesting if the members would give their experience. I supposed that the old-fashioned method of using a pessary had been discarded a generation ago. I practically never use internal appliances for any cause whatever, that is, extending over any period of time. I have never used a stem pessary. I don't see just what good it can do. I have seen a great deal of harm result from the use of pessaries, and therefore, I have not used them.

Dr. H. P. Jack, Canisteo, N. Y.: Often the uterus will either raise children or raise something else. We often see in women engaged in mental work the most severe suffering from dysmenorrhea and scanty menstruation. I have in mind a woman who, in spite of the most careful treatment, had become a nervous wreck and who had not menstruated for eight months. Following the method of Dr. Carstens, I used a stem pessary and since that time she has menstruated, not profusely, but regularly. She has developed from a nervous wreck to a healthy, robust, well-feeling young woman. I could report several other cases in which the results have been equally striking, in which women have been transformed, so to speak, from invalids to healthy capable persons.

Dr. A. E. Benjamin, Minneapolis: I have been using the Outerbridge speculum instead of the stem pessary, although I have used Dr. Carstens' stem pessary in several cases and must report good results in some of them. We must be sure that a case of amenorrhea is due to a lack of development of the uterus or of the ovaries. Dr. Carstens has thrown out a few suggestions in regard to the use of the pessary, but we must be absolutely sure that there is not an undeveloped condition of the adnexa, particularly of the ovary. I have seen a number of cases in which a fibrocystic degeneration was taking place; and it must be remembered that amenorrhea will occur on that account. In some of these cases laparotomy was done, the ovaries were resected, cysts removed and menstruation and pregnancy have followed. In cases of dysmenorrhea I have used the Outerbridge speculum introduced just previous to the menstrual flow. Its spring-like action keeps the cervix open. It is one of the best instruments we can use at that time. Also in dysmenorrhea we must be sure that the difficulty is not due to some condition outside of the uterus, that is, in the pelvis. For sterility the same instrument can be used. A few cases I can report in which pregnancy occurred by the use of the Outerbridge speculum, but in most cases I think that Dr. Carstens' stem pessary can be used with greater satisfaction. I believe with Dr. Kelly that nothing should be introduced into the uterus to be left there for any length of time. But when one can restore the function of the uterus and produce a more normal mental state by the use of some of these things, I think their employment is justified.

Dr. J. H. Carstens, Detroit: How can any one judge of a thing he has never used. Thirty or forty years ago it was a serious matter to use these pessaries; they were inserted and severe inflammation was the result. To-day we see great benefit resulting from their use. I have women traveling all over the world wearing these stem pessaries, and able to do all kinds of work.

OPACITIES OF THE CORNEA

THEIR FREQUENCY IN CHILDHOOD FROM PREVENTABLE CAUSES AND THEIR EFFECT ON VISION *

COLMAN W. CUTLER, M.D.
NEW YORK.

Ophthalmology has been regarded as a field not distinct from general medicine, but comprising problems such as refraction and special surgery, which require so thorough a training as to deter the practitioner of medicine. It is obvious that this attitude is deplorable, as it tends to make the specialist in reality narrow as well as to deprive the practitioner of information at first hand which is often of great value.

The ophthalmoscope has become an instrument of precision in the hands of every careful diagnostician. Gower's "Medical Ophthalmoscopy," the excellent translations of Haab's atlases, and articles by Bull, de Schweinitz, Duane, Knapp, and Risley, who has drawn attention to the importance of hygiene in the care of the eyes of school children—these writings and many others have awakened an interest in ocular problems, and the questions which this paper will raise will, it is hoped, justify its presentation before a society which welcomes all information relating to the welfare of children.

In the excellent address of the Chairman, stress has been put on the importance of foresight. In the care of children, as in no other field of medicine, conditions of nutrition and of the inheritance of a disposition to disease must be anticipated and controlled before the precious moment has passed and the tendency becomes disease.

Some of the special problems met in aural disease are now recognized by the general practitioner and faced with confidence. The skin is a field full of suggestion which we study for the most varied signs of general disorder and of lessened resistance to external irritation. We do not need to know the nature of eczema or of the various forms of dermatitis to grasp to some useful degree their significance.

The meaning of the surface of the eye should be equally patent; and if it is studied as part of the surface of the body, containing in its small area some of the same problems met elsewhere, it will yield information equally significant.

In order to make quite clear the nature of the lesions to be considered, it will be necessary to review briefly the structure of the cornea. The surface consists of six or eight layers of stratified epithelium, like the epidermis, and, like this, it is renewed if scratched, without the formation of a scar. In reptiles that shed their skin, it is cast off with the external cuticle. Beneath this is Bowman's membrane, the external limiting layer. This is a firm and resistant membrane without apparent structure, which forms a very efficient protection to the stroma beneath from foreign bodies. The resistance of this membrane is evident when a foreign body penetrates the epithelium and lodges in it, and has to be picked out with a needle or when it is necessary to apply some strong antiseptic to an infection of the superficial layers. Without it, the transparency of the cornea would be in constant danger. If Bowman's membrane is destroyed, it is not renewed. Although the epithelium is loosely attached to it, this membrane is firmly connected with the corneal tissue or stroma beneath, which is formed of fifty or sixty layers of fibrous tissue inclosing spaces which contain fixed cells and lymph from the scleral vessels, which forms the only source of nutrition of the cornea.

Posterior to the stroma is Descemet's membrane, the posterior limiting layer which has on its surface, in contact with the aqueous humor, a single layer of endothelial cells. The anterior and posterior limiting layers are impervious to fluid and protect the stroma from infiltration from without and from within.

This very elementary sketch may serve to refresh the memory. In dealing with the eyes of children, it is important to remember that, while epithelial damage is not vital, an infection or injury which passes Bowman's membrane will leave an indelible trace, which is a menace to vision if it lies in the area of the pupil.

Before the child is excited by an attempt to separate the lids, the surface of the eye should be inspected if possible by daylight before a window, so that the even surface of the cornea and its reflecting properties may be studied as the eye follows the finger. Any distorting of the bars of the window, for instance, will indicate an unevenness, which is a sign of past or present trouble.

The examination of the eyes of a resisting child is not always easy, but if there is a history of eye trouble, or if there is secretion on the lashes, or if the child shuns the light and has evident discomfort and cries when attempt is made to separate the lids, the cornea must be inspected thoroughly. This requires a good light and a lens, not to be used as a magnifying glass, but as a means of focusing the light on the cornea—and any one who has to look at the eye should never be without a lens.

An assistant who can hold the child and steady the head is also needed, although the better plan usually is to hold the child's head in one's lap, steadying it between the knees, while the nurse controls the body and arms.

The best elevators are the fingers, but pressure on the cornea must be avoided and this needs practice, especially when the photophobia and blepharospasm is intense, as is often the case in phlyctenular keratitis. If it is necessary to use the elevator of Desmarres, great care must be taken to avoid scraping the cornea.

The control of the child, the arrangement of the light and of the lens, and the manipulation of the lids with due regard for the already inflamed eye may seem difficult, but the importance of these measures can not be exaggerated. An attempt to describe them in detail may be spared, since a very little practice will suggest modes of procedure which will vary with the case. Every book on ophthalmology deals with this subject. Among many excellent works, Haab's "Atlas of the External Diseases of the Eye," edited by de Schweinitz, will be found especially useful for the general practitioner.

There are three points to be considered in examining the cornea, all familiar but not the less important: the corneal reflex, the smooth surface and the transparency. Any clouding of the normal glistening reflex indicates an active process, edema or infiltration. If, with this, there is a defect or depression of the surface, an ulcer is present in an active stage. If the defect glistens, however, showing that the epithelium is restored, the ulcer is in process of repair, or there is a cicatrix. If the infiltration is deeper, beneath Bowman's membrane, the surface may be intact as in the early stage of a phlyctenule or in an interstitial keratitis of syphilis.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909

The formation of vessels beneath the epithelium in pannus or fascicular keratitis and the deeper vessels in interstitial keratitis are to be noted. Ciliary injection and hypopyon should not escape attention and their significance is well known.

It is my purpose to impress on the general practitioner the importance of an early recognition of small lesions of the cornea. In their beginnings, most ulcers can be controlled without serious damage to the eye. Ulcers complicating gonorrheal ophthalmia do not always yield to treatment, however, but here, too, an early and vigorous treatment of the disease will usually prevent such unhappy results.

The importance of Credé's method is acknowledged and the immense progress in recent years toward the prevention of blindness is a matter of sincere congratulation. It rests with pediatricians as much as with ophthalmologists to see that laws are passed and that incompetent nurses and midwives and ignorant parents are not allowed to lose precious time in futile methods before the sovereign remedy, nitrate of silver, is used.

All cases of infants with purulent discharge should be treated as if they had gonorrhea, even if the gonococcus is not found at the first examination. The careful use of nitrate of silver does no harm and may do incalculable good.

The milder silver preparations, argyrol and protargol, should be used as adjuvants only and should not supplant the nitrate of silver in cases that show virulence. In epidemics of measles in a large children's hospital, during the past five years, these milder silver preparations have been used in all cases with secretion, and in no such case has a corneal ulcer developed, although previously such complications were not infrequent.

An ulcer of the cornea in gonorrheal ophthalmia may occur at the margin where the swollen conjunctiva overhangs the cornea or near the center where the nutrition is poor. The ulcers at the margin may be due to the accumulation of secretion beneath the swollen conjunctiva, which makes it very difficult to inspect and cleanse the cornea without abrading the epithelium. The central infection is due in many instances to injury received during examination or cleansing.

It is not the purpose of this paper to deal with treatment in these cases; but the importance of a thorough examination and of care in opening the lids and in removing the secretion can not be exaggerated.

The nutrition of an infant with ophthalmia is often a problem of greater difficulty than the treatment of the disease itself. In a recent paper[1] on this subject attention was called to this important point and reference was made to an article by Lobenstine and Harrar, who demonstrated the ill effects of gonorrhea in the mother on the early nutrition of the child. A question which is often raised is whether the child may remain at the breast. If the infant is nursed by its own mother and her intelligence permits proper care being taken to protect her own eyes, this course should be followed, but in an institution it is rarely possible without assuming a grave responsibility.

Phlyctenular conjunctivitis and keratitis has been a mooted point in ophthalmology, as is eczema in dermatology, and the two conditions have been associated as if they were of the same nature. This only adds to the confusion because it brings under one head two conditions of whose etiology little is known and which actually have little in common.

Phlyctenules are small nodules or collections of round cells beginning beneath the epithelium and frequently beneath Bowman's membrane, as has been shown by Baas. They are not vesicles, as their archaic name implies. No organisms have been found in the early stages, although staphylococci are numerous in their later development. It is probable that they arise from internal irritation, i. e., endogenously from toxins, or, as has been well expressed by Axenfeld, that they indicate the manner in which the conjunctiva, of scrofulous persons especially, reacts to various forms of irritation.

These eruptions are of importance because they appear insidiously and are often not brought to our attention until permanent damage has been done to vision. They are very frequent, especially in ill-nourished children of the poorer classes whose eyes have been neglected, particularly in those with adenoids, whose nares are obstructed and crusted, or who have eczema of the scalp and blepharitis. Undoubtedly ulcers of the cornea arise from direct infection from these sources, but the early stages of phlyctenules are quite characteristic and should be regarded as a probable indication of tuberculosis. After a phlyctenule comes to the surface as an ulcer and is secondarily infected, it loses much of its distinctive appearance, but the deeper infiltration and the vascularity are always suggestive of its origin.

In twenty cases examined recently, in addition to several with manifest tuberculosis of bones or glands, a positive reaction to tuberculin was noted in all except two cases, which were superficial ulcers and not typically subepithelial. Axenfeld has made similar observations, and Verhoeff, whose views of the relation of phlyctenules to tuberculosis have been quoted in the article previously referred to, is strongly of this opinion. These true phlyctenules should then be classed as stigmata of tuberculosis, and, as they not infrequently occur in apparently healthy children, they offer an important indication for further investigation and general treatment.

A characteristic of phlyctenules is their tendency to recurrence during any depression of vitality and their disappearance with tonic treatment and improved hygiene. With the great progress that has been made in recent years in school inspection and hygiene, this very important and interesting condition has diminished during the school age, but in the early years it is frequent, and the scars left on the cornea are too often a cause of impaired vision and lessened usefulness in later life. One meets with young men and women who wish to become stenographers or teachers or nurses, and whose intelligence justifies the ambition, but whose defective corneas make the continued eye work a source of unnatural effort and ultimate discouragement. Many cases of unilateral squint are caused by a minute fleck on the surface of the squinting eye. These local results of the fleeting and often ignored eruption in infancy are very important, and I am glad to be able to call your attention to their broader significance as a sign of a dyscrasia against which we are making a united contest.

Syphilis is a potent cause of corneal opacities and the traces which it leaves are as typical for the diagnosis of that disease as are Hutchinson's teeth. In the initial stages of interstitial keratitis, the cornea is intensely vascular, but the vessels are deeper than in pannus following trachoma or scrofula. These deep vessels are believed to be permanent, remaining visible after all infiltration has been absorbed. as fine branching twigs, extending from the limbus into the corneal tissue. They are seen when the pupil is dilated, with a + 20 D. lens in the ophthalmoscope, if the observer approaches close to the patient and throws the light into his eye. This sign of an early syphilis should be available to the general practitioner, as it is sometimes present when other symptoms are absent and may throw light on obscure conditions of nutrition.

---

[1] Cutler: Lesions of the Cornea in Gonorrheal Ophthalmia and Phlyctenular Keratitis, Am. Jour. Obst., 1909, lix, No. 4.

To summarize this paper in a few words, I have tried to show the importance of the normal cornea and to define the changes which have a general significance. The methods of examination have been indicated and certain precautions in the manipulation of the lids have been emphasized. The method of examination with a lens by means of oblique illumination is easily acquired and should be practiced in all cases in which the eyes show signs of irritation and as a means of diagnosis in obscure cases in which tuberculosis or syphilis is suspected. Especial stress has been laid on the early recognition of ulcers and infiltrations which, if neglected, may permanently impair the sight.

Finally, to repeat a familiar idea, the importance of recognizing latent tuberculosis not only for the sake of the individual, but of society, is obvious. Scrofula has been a useful term, but must give way to a more definite expression. It is not needed where tuberculous glands or other lesions are present in which the bacilli may be demonstrated; and in other cases if the patient react to tuberculin, and have phlyctenules or other signs of a toxemia without a discoverable focus, it may be convenient to speak of latent tuberculosis or of tuberculous toxemia.

It has been said that most human beings have successfully resisted tuberculous infection, and the corollary is that, if the condition had been recognized soon enough, the number of those who have not successfully resisted it might have been greatly diminished.

The question of the wider use of tuberculin for diagnosis in schools and especially in children's hospitals is so involved with social and economic considerations that it can not be dealt with in this paper. Nor does it belong to a discussion devoted to ocular matters, but, like most medical problems, it overlaps many fields, and the opinion of this Section would have great weight.

Certain members of the race are the hosts of organisms to which they are in a measure adapted or which they tolerate, but which are still dangerous to others.

Unquestionably "typhoid-carriers" are a very great factor in the dissemination of typhoid; so in venereal diseases, those in whom the disease is latent are most dangerous, and in tuberculosis especially no effort should be spared to discover the unsuspected cases. We may doubt whether the prophecy of Professor Lankester in his Romanes lecture of 1905—"that the knowledge of the causes of disease has become so far advanced that it is a matter of practical certainty that, by the unstinted application of known methods of investigation and consequent controlling action, all epidemic disease could be abolished within a period so short as fifty years"—will be realized, but the ideal of eugenics so recently raised must be held in mind and all possible effort made to realize it.

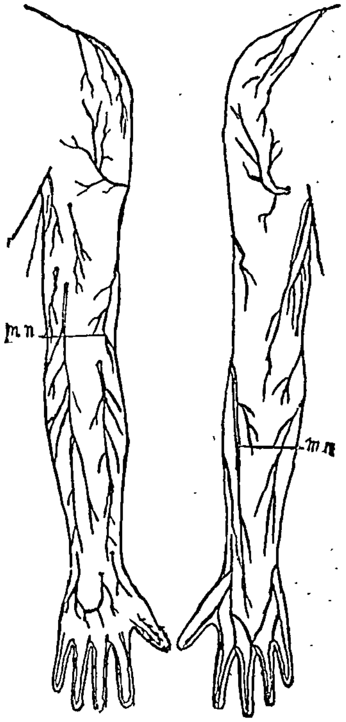
Asclepiades.—Without any increase of positive knowledge, Asclepiades and the Arabs cut loose from the teachings of simple clinical experience. Particularly the latter built up a confused mass of therapeutic measures. Their numberless old and new medicinal internal and external aids and appliances remind us of the detrimental activity displayed by the worst class of our wholesale nostrum vendors.—A. Jacobi, in *Monthly Cyclopedia and Medical Bulletin.*

Clinical Notes

AN ISOLATED NEURITIS OF A SENSORY FILAMENT OF A PERIPHERAL NERVE-TRUNK

ALFRED GORDON, M.D.
PHILADELPHIA

The peripheral nerve-trunks of the extremities, being composed of mixed motor and sensory fibers, when in a state of irritation or inflammation, will give rise to both motor and sensory phenomena. This is a common observation. An isolated involvement of either motor or sensory nerve fibers is sometimes observed. We are very familiar with motor neuritis and sensory neuritis. For example, in multiple neuritis caused by lead intoxication, motor phenomena (palsy) are almost exclusively present and the sensory disturbances are usually *nil.* In syphilis a sensory multiple neuritis may be alone present for a long time. Alcoholic neuritis may be also exclusively sensory.



Innervation of the arm; posterior aspect on the left, anterior on the right; M.N., external inferior cutaneous branch of musculospiral nerve.

If now we consider the individual branches of the main nerve-trunks of the extremities isolated, we find that palsies or inflammations of the motor divisions are not rare, but a neuritis of a sensory filament, judging from the neurological literature, is certainly a great rarity. Within the last eight months four cases came under my observation, all presenting a singular similarity in the localization, also in subjective and objective manifestations, and pointing to an involvement of the inferior cutaneous branch of the musculospiral nerve. The absence of such a record in the literature warrants the publication of my observations.

My four patients are two men and two women. Three of them are of middle age and one (girl) 23 years old. One man is a barber, the other a cutter (tailor), and the two women do housework. None of them except the girl uses alcohol. The latter uses it quite freely.

When they first consulted me, they all complained of a pain immediately behind the external condyle of the right arm. Curiously enough, in every one of them the right arm was involved. When the forearm is in pronation there is no pain. But as soon as slight pressure is made over the above spot at a distance of about a half of an inch above or below, pain was exquisite. The condyle itself is not tender. As to spontaneous or induced movements of the forearm, unless they are violent they are all painless with the exception of supination, which in three of my cases is slightly painful and in one not at all painful. The barber especially states that, while shaving or cutting hair, every time he would have to turn the hand in an outward movement, pain would appear in the mentioned area so that he was obliged to discontinue his work for a few moments. In addition to the pain brought on by pressure or by certain movements, there is also a spontaneous pain behind the external condyle and radiating down the posterior aspect of the forearm on its middle and external sides at a distance of a third of the limb. This pain is paroxysmal, comes on even when the arm is at rest and has the character of a neuralgic pain; that is, it appears suddenly without any apparent cause and is sharp and lancinating.

A careful examination for general sensations of the area of distribution of the lower cutaneous branch of the musculospiral nerve (see illustration) showed in the two men a hyperesthesia, and in both women a hypesthesia to touch, pain and temperature senses. As is well known, the dorsal external cutaneous branch of the musculospiral nerve, passing down between the outer and inner heads of the triceps, divides near the elbow into its upper and lower branches. The upper branch, the smaller, supplies the skin over the lower half of the outer and anterior aspect of the arm. The lower branch, the largest, runs behind the external condyle and supplies the skin of the middle of the back of the forearm, anastomosing with the medial internal cutaneous and musculocutaneous nerves. The partial preservation of sensibility in my patients over the area of distribution of the lower cutaneous branch is probably due to its anastomosis with other sensory branches, but why hyperesthesia should be present in some cases and hypesthesia in others is difficult to explain with certainty. The difference probably depends on the degree of inflammation of the nerve; with a greater degree of inflammation, hyperesthesia is likely to be present, while with a less degree hypesthesia will be the result. This contention finds its corroboration to a certain extent in the course of the neuritis. The two women whose affected areas were hypesthetic recovered in a comparatively short time (from two to four weeks), while the men with the hyperesthesia suffered from four to six months. To sum up, the affection presented exclusively sensory phenomena, namely, tenderness of a sensory nerve-trunk, disturbed objective sensory symptoms (hyperesthesia and hypesthesia) to all forms of sensation over the area of distribution of that nerve, spontaneous pain of a neuralgic character, commencing immediately behind the external condyle and radiating down the back of the forearm at a certain distance. No motor phenomena could be observed in the affected area and trophic disturbances were equally absent. The entire pathological picture was solely in the domain of one sensory branch of the musculospiral nerve.

It was mentioned above that pain could be brought on only by supination in three of the cases. The reason of it lies probably in the fact that the supinator longus arises from the upper two-thirds of the external condyloid ridge of the humerus and from the external intermuscular septum of the arm. The lower branch of the dorsal cutaneous branch of the musculospiral nerve, which is involved here, also separates from its upper branch at the level of the intermuscular septum. There is consequently great proximity of the origin of the nerve and muscle; a display of the latter will naturally irritate the nerve which is in a state of inflammation.

The etiology of this neuritis is probably that of neuritis in general. None of my patients could tell whether a trauma had been sustained or not; perhaps a slight trauma did exist, but passed unnoticed. Exposure to cold may have been a factor: the two women were obliged to do general housework; their arms were frequently, they say, in contact with cold water. Have the occupations of the male patients anything to do with their sensory neuritis? They said, however, that they were obliged to discontinue their work, as the latter invariably caused pain. A complete rest gave complete relief. While it is easy to conceive that some stretching of tissue and of cutaneous nerves takes place when the forearm is in a state of flexion for a long time (and this is precisely the situation with barbers and cutters), it is nevertheless difficult to attribute the neuritis exclusively to this factor, as otherwise a sensory neuritis of that particular nerve would be a frequent occurrence, which is, of course, not the case. The two male patients and the middle-aged woman have been suffering from rheumatism for years. The cutter had once an attack of occupation cramp in the right hand. The barber had once a paresis in the right hand following a cold bath. The girl is an alcoholic and perhaps syphilitic. All these predisposing factors probably played a certain rôle in the etiology.

As to the treatment, Bier's method of induced hyperemia was apparently successful in the middle-aged woman, but unsuccessful in the others. Complete abstention from work and exposure, hot baths locally applied and aspirin internally gave considerable relief. It is practically the same treatment as used in other forms of neuritis.

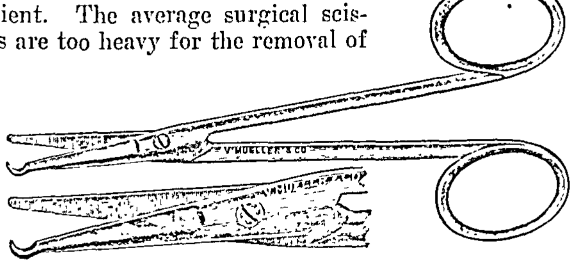
STITCH SCISSORS FOR EYE, EAR, NOSE AND THROAT

FRANK R. SPENCER, A.B., M.D.
Instructor of Rhinology and Laryngology in the University of Colorado
BOULDER, COLO.

I have long felt the need of a pair of scissors which would enable me to remove stitches from wounds more rapidly than do ordinary scissors and at the same time with less inconvenience to the patient. The average surgical scissors are too heavy for the removal of stitches, and they often permit the sutures to slip over the end of the engaging blade.



The scissors here illustrated enable one to remove stitches from the conjunctiva, lids, mastoid, turbinate, etc., with a minimum of pain.

Physicians' Block.

A CIRCUMCISION OPERATION FOR THE YOUNG

SAMUEL E. NEWMAN, M.D.
ST. LOUIS, MO.

The text-books on surgery seem to imply that a circumcision is the simplest of procedures. The operation, however, is often troublesome. Postoperative complications do occur. The penis may become edematous to the point of making urination difficult. In certain cases the swelling and induration subside only after the removal of the stitches. More or less oozing of blood may persist for days or a hematoma of no small size delay the union of the parts. Inflammation in the tissues may be marked; this may abate rapidly or pass away only after the skin has broken and discharged its pocket of pus.

There is in nearly every circumcision some swelling of the organ. When the purse-string suture was advocated this condition was marked. If many interrupted stitches are placed close together so as to secure too perfect a coaptation of the edges the edema appears very promptly after twenty-four hours. A few loosely tied stitches give a decidedly better result. The query arose why sewing was employed at all, at least in the young. Cannot the skin be cut so that the edges are sufficiently approximated for a good result? If this can be done, the blood and lymph can more readily find a vent; the trauma to the tissues resultant from handling with the tissue forceps and needle and thread will be minimized; the reaction from the operation less disturbing. In a series of cases the operation has been carried out with this idea in mind and the result has been most satisfactory. The wound required very little attention; the comfort of the patient was not interfered with; a good result was obtained in five to ten days. I recommend the operation here offered as efficient, easy and quick.

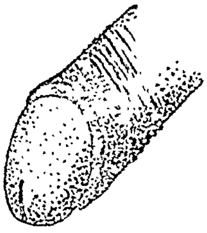

Fig 5.

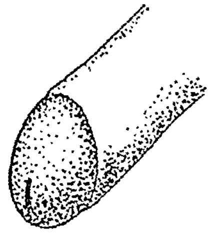

Fig. 6.

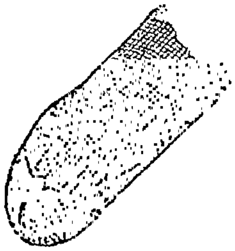

Fig. 8.

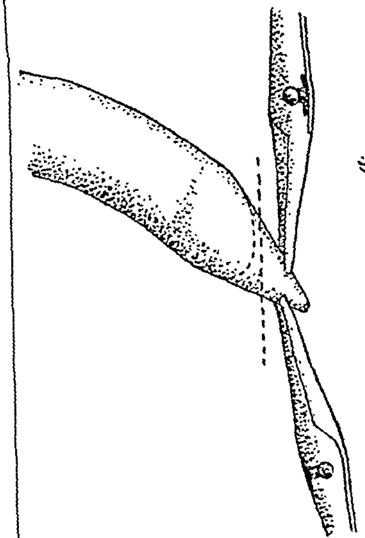

Fig. 2.

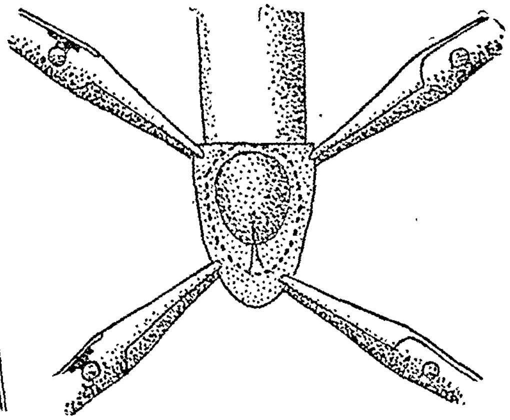

Fig. 4.

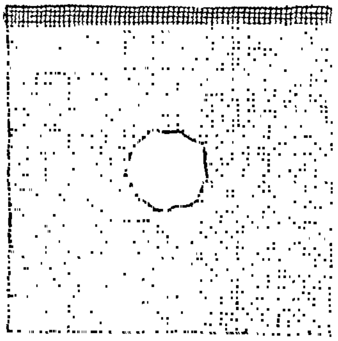

Fig. 7.

STEPS IN THE OPERATION

1. The penis is held in place by two snaps, which pinch the skin of the organ between the selvage edge of two lengthwise adjusted towels (Fig. 1).

2. When the penis is in position, the location of the glans is determined and the amount of superfluous prepuce noted. One hemostat is applied above and one below in an oblique line so that more skin is removed from the under surface than from the dorsal. The hemostats pull the foreskin forward and then the skin is cut off with straight scissors along the dotted line, as shown in Figure 2. If the tissue is correctly removed the skin edge will retract to the corona. In the removal of the foreskin of a babe in the first months of life it is well to bear in mind that the parts are all diminutive and that the entire corpus is not much longer than the glans. Carelessness in this consideration results in an almost complete denudation of the organ; the skin retracting to the base of the penis.

3. The inner skin layer, or mucous membrane layer, as it is sometimes called, is slit down the dorsal surface to within one-fourth of an inch of its attachment (Fig. 3).

4. The edges of the inner layer are held with a few hemostats to facilitate the removal of all but a small collar at its attached edge. The dotted line in Figure 4 indicates the line of excision followed by the scissors.

5. The little bleeding vessels, two to four in number, are caught up and in every case tied with plain No. 00 catgut. This saves much postoperative annoyance.

6. Figure 5 shows the skin drawn up on the corpus away from the corona. Figure 6 is the result when the skin is allowed to come forward to the corona, where it meets the trimmed margin of the mucous membrane layer.

7. A piece of gauze with a small opening at its center is steeped in melted 10 per cent. boracic petrolatum and applied to the parts at the completion of the operation (Figs. 7 and 8). The dressing is changed if it comes off and may be discarded completely on the third day. The parts are then protected by boric ointment.

CHOICE OF ANESTHETIC

The use of cocain in children is not advisable, and the general anesthetic is probably the most desirable method. Infants only a few years old may be held by two assistants and the operation done without any anesthetic. I desire to call attention to the method of bandaging the child to a board after the Indian fashion of strapping the papoose; for this purpose a narrow cushioned board and a few bandages are all that is required to hold the child firmly in place until the operation is ended.

OBJECTIONS TO THE OPERATION

It may be asked, what happens to a patient operated on in this manner if the penis becomes erect.

The parts permit the easy stretching of the wound and there are no stitches to pull open or to cut through the tissues. When the erection has subsided the tissues contract and the edges of the wound are approximated in a satisfactory manner.

Against the operation may also be mentioned the fact that much of the wound heals by granulation. While this is true, a wound which is difficult to keep free of infection should not be sewed up tight.

The object of this paper is not to lay claim to originality, but to bring before the profession a procedure which has many advantages over the operations in vogue and one which gives most pleasing results when done in patients before the age of ten or twelve years.

4900 Berlin Avenue.

A SIMPLE, RAPID, AND ACCURATE METHOD FOR THE DETERMINATION OF AMMONIA AND ACETONE IN URINE

ROSCOE W. KING
LAS ANIMAS, COLO.

Many of the propositions of chemistry, like those of mathematics, are susceptible of easy demonstration. To this class belong the following:

PROPOSITIONS

1. When 50 c.c. of fluid containing 0.5 gram of sodium carbonate, 50 mgm. of ammonia, and 25 mgm. of acetone is distilled, the entire amount of the NH_3 and $CH_3.CO.CH_3$ will pass over with the first 25 c.c. of distillate. This proposition is certainly true, but it is equally certain that it is not generally known. If it were, we should not be directed, as we usually are by text-book writers, to collect the acetone from urine by distilling 100 c.c.—or less—until seven-eighths of the fluid has passed over.[1] Nor should we have been cautioned to test the subsequent distillate for acetone.

2. When 10 c.c. of a solution containing from 0.5 to 8 per cent. of urea is diluted with 40 c.c. of water containing 0.5 gram of sodium carbonate and distilled so that 25 c.c. will pass over in from four to eight minutes after boiling begins, the distillate will contain one half as many cubic centimeters of decinormal ammonia as the solution contains grams of urea per 100 c.c.; i. e., the per cent.. of urea divided by two will give the number of cubic centimeters of decinormal ammonia resulting from ureal decomposition. The exact amount of the ureal ammonia will vary with the time required in collecting the distillate, the amount being greater as the time is longer. When, however, the time required ranges between four and eight minutes, as in practice it probably always will, the constant (per cent. urea divided by 2) may safely be used, for all clinical purposes, as expressing the amount of ammonia produced by the action of the sodium carbonate on the urea.

3. The presence of such an amount of ammonium sulphate as could occur in neutralizing the distillate from 10 c.c. of urine with sulphuric acid has no effect whatever on the accuracy of Huppert's modification of Messinger's method for estimating acetone. Ogden,[2] Simon[3] and others make the erroneous statement that acetone cannot be estimated in the presence of ammonia.

4. The presence of such quantities of alcohol as may be recovered from urine, or as may be introduced with the indicator used in estimating ammonia, in no way affects the determination of acetone by the iodoform (Messinger-Huppert) method.

On the above propositions is based the following simple, rapid, and clinically accurate method for the determination of ammonia and acetone in urine. It will usually only require about thirty minutes to carry out the process.

PROCESS

Apparatus Required.—The apparatus at present used in this laboratory is that shown in the accompanying drawing. It represents an outlay of about one dollar, and weighs, excluding the battery jar, only 175 grams. It is light, durable, convenient, and gives good results.

---

[1] Autenrieth (Detection of Poisons, page 42) says: "Acidify from 200 to 50 c.c. of the urine with a few drops of sulphuric acid and distil. Collect 20 or 30 c.c. of distillate. This will contain the entire quantity of acetone in the urine."

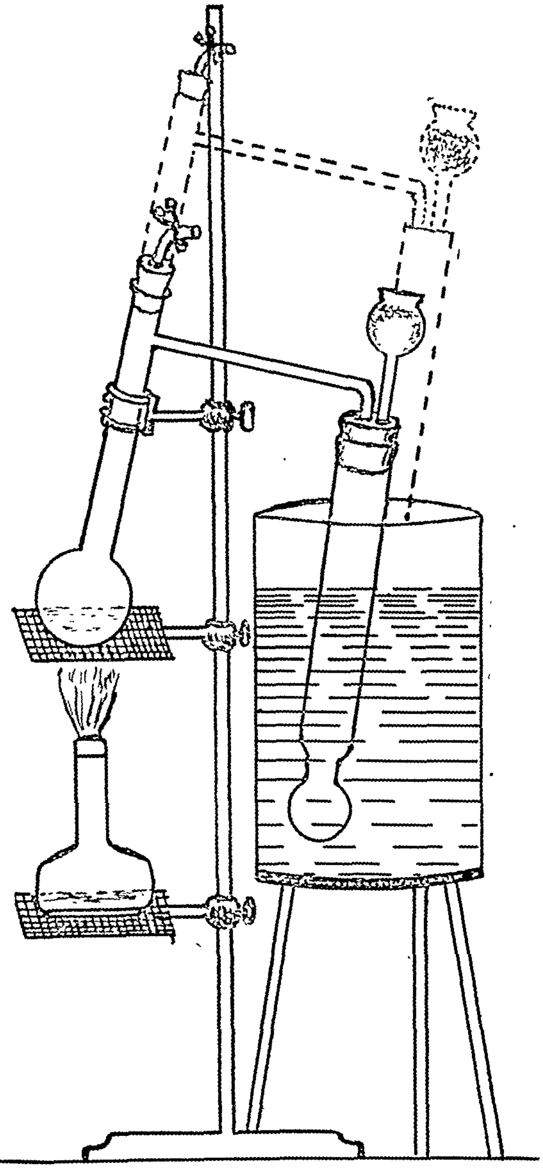
[2] Ogden: Clinical Examination of the Urine, page 176.

[3] Simon: *Clinical Diagnosis*, page 532.

Determination of Ammonia.—The apparatus being in the distilling position shown in the illustration, the battery jar is filled with water until the surface of the water is about 30 mm. below the top of the receiving tube. The apparatus is then raised into the second position, shown by the dotted lines, and held there by means of the burette clamp. The receiving tube is then removed and 25 c.c. of decinormal sulphuric acid from a pipette is poured into it. The glass wool in the thistle-headed funnel is thoroughly moistened by pouring several cubic centimeters of distilled water over it, the excess being allowed to flow into the battery jar. The receiving tube is now firmly fixed, the rubber stopper carried by the stem of the distilling flask, and the apparatus lowered into its original position. By means of a long-stemmed thistle funnel 10 c.c. of the urine[4] are introduced, followed by 40 c.c. of water containing 0.5 gm. of sodium carbonate. The distilling-flask is immediately closed and heat applied. This should be of such intensity as will bring over 25 c.c. of distillate in from four to eight minutes after boiling begins. A Barthel's alcohol or gasoline burner or a Bunsen gas burner will answer equally well. During the distillation it is advisable to stir the water in the battery jar once or twice, as otherwise the water near the surface will become unduly heated, while that near the bottom will remain cold.[5] When the distillate reaches the 50 c.c. mark on the receiving tube the source of heat should be removed, the air-cock on the distilling flask opened, and the glass wool washed by pouring about 25 c.c. of distilled water through it into the receiver. Now the apparatus is raised into the second position, the receiver removed and its contents transferred into a flask containing about 200 c.c. of distilled water. A few drops of cochineal,[6] or, wanting this, alizarin red, are added as indicator, and the decinormal sodium hydroxid solution run in[7] from the burette until a permanent change of color results. The number of cubic centimeters of the decinormal sodium hydroxid required deducted from 25 will give the total number of cubic centimeters of decinormal ammonia contained in the distillate. From this amount are deducted one-half as many cubic centimeters as the per cent. of urea which the urine contains, and the remainder multiplied by 0.017. This will give the per cent. of ammonia contained in the urine; i. e., grams of NH_3 per 100 c.c. This may be represented in formula as follows:

$$Y = 17\ [25 - (X + \frac{\%\ \text{urea}}{2})]$$

In this formula Y is the number of milligrams of ammonia contained in 100 c.c. of urine, when X is the number of c.c. of the decinormal NaOH required to neutralize the excess of acid.



The apparatus shown in the drawing consists of the following: 1. A 250 c.c. Baloc distilling flask fitted with a rubber stopper through which passes a short glass tube, over which is fitted a short rubber tube. This air-cock arrangement is opened or closed by means of a Hoffman's tubing clamp. The remote end of the stem of the distilling flask is bent as shown, and is tightly fitted into a two-holed rubber stopper; the end of the tube should reach 25 or 50 mm. below the stopper. 2. Through the second hole of this stopper is passed the stem of a thistle funnel, the stem having been filed off to a length of about 75 mm. The head of the funnel is loosely packed with glass wool. 3. A large (100 c.c.) potato culture tube carrying a mark around the circumference at the 50 c.c. point. This is obtained by pouring 50 c.c. of water into the tube and marking with a wax pencil. A file being subsequently used. 4. A three and one-half liter battery jar. The use of the tripod permits the water in the jar being changed without the slightest inconvenience. The dotted lines show the second position of the apparatus. This allows the receiving tube to be easily removed or placed in position.

---

[4] If the urine cannot be had soon after it is voided it should be preserved with a few drops of chloroform. If more than a trace of albumin is present it should be removed before distilling.

[5] Three distillates may be collected without changing the water in the battery jar, provided it has a capacity of three or four liters.

[6] An excess of the indicator must be avoided. The best results may be obtained by adding a very small amount—say half a grain—of the powdered cochineal.

[7] As a simple and accurate means [illegible] tric acid and alkali solutions I suggest the [illegible] Dissolve about 50 grams of sodium hydroxi[illegible] in 1,100 c.c. of distilled water. 2. Accurately weigh 3.3 grams of chemically pure ammonium sulphate and dissolve in sufficient distilled water to make 500 c.c. 3. Dilute 25 c.c. of formalin (40 per cent. HCOH) with about 75 c.c. of distilled water. Add several drops of phenolphthalein and then run in the sodium hydroxid solution from the burette until a faint pink color is permanent. 4. Measure accurately 25 c.c. of the decinormal ammonium sulphate solution into a small flask and add about 15 c.c. of the neutral formalin solution. This liberates exactly 25 c.c. of decinormal sulphuric acid. Now add a few more drops of the phenolphthalein and run in the sodium hydroxid from the burette until a permanent, faint pink color appears. Repeat the experiment and from the data obtained correct the remaining sodium hydroxid solution by adding to 1,000 c.c. of it a sufficient amount of distilled water to make 25 c.c. of it correspond to the acid liberated by an equal volume of the decinormal ammonium sulphate solution. From the resulting decinormal sodium hydroxid solution can then be prepared the decinormal sulphuric acid. Inasmuch as ammonium sulphate can easily be obtained of great purity, and contains no water of crystalization, it is believed that it will afford a more accurate means of preparing decinormal solutions than either oxalic acid or sodium carbonate. Decinormal solutions made in this way have, in this laboratory, been found to agree exactly with those standardized gravemetrically.

Determination of Acetone.—The neutral fluid obtained in the ammonia estimation is, if necessary, made up to 300 or 350 c.c. with distilled water and 10 c.c. of decinormal iodin added, followed by 10 c.c. of a 10 per cent. aqueous solution of sodium hydroxid. This is allowed to stand for fifteen minutes; then 10 c.c. of a 10 per cent. (by volume) sulphuric acid solution are added. The free iodin is then determined by means of decinormal sodium thiosulphate solution.[8] This is run in from the burette until only a light brownish-yellow color remains. At this point ten or fifteen drops—not more—of the starch solution[9] should be added and the thiosulphate solution should be added by degrees until the blue color is just discharged. The number of cubic centimeters of the thiosulphate solution required deducted from the total number of cubic centimeters of the iodin solution used will, when multiplied by 9.7, give the number of milligrams of acetone contained in 100 c.c. of the urine. One c.c. of decinormal iodin combines with 0.97 mgm. of acetone. But as only 10 c.c. of urine were used, the number of cubic centimeters of iodin required is multiplied by 9.7 to get the number of milligrams of acetone in 100 c.c. of urine.

It need hardly be said that the above method for estimating acetone is proposed as being clinically accurate, and that it is reliable. experiments leave no room to doubt. How nearly the results may be made to approach absolute accuracy is not definitely known at present. It is not thought probable that the error will ever exceed 2 or 3 mgms. of acetone in 100 c.c. of urine. Variations of this magnitude may easily occur in perfect health, and hence, from a clinical standpoint, are of no importance whatever. The method is, of course, not applicable to urines which contain sugar, since acetone is produced when dextrose is treated with boiling alkaline solutions. If the urine contains as much as 5 or 10 per cent. of sugar it would, when distilled as above with the sodium carbonate solution, yield about 5 mgm. of acetone as a result of the decomposition of the carbohydrate.

In the presence of sugar the following procedure should be adopted. It requires but little more work and no more time: (1) Dilute 10 c.c. of urine with 40 c.c. of water. Add enough 36 per cent. acetic acid—about 1 c.c.—to make strongly acid to litmus. Place 25 c.c. of water in the receiving tube. Distill until 25 c.c. come over. The distillate and washings from the glass wool is made up to about 300 c.c. and the acetone determined as directed above. (2) While waiting for the iodoform to separate take an additional 10 c.c. of the urine and dilute with 40 c.c. of water containing 0.5 gram of anhydrous sodium carbonate and, having placed 25 c.c. of decinormal sulphuric acid in the receiving tube, distill over 25 c.c. Estimate the ammonia as directed above.

If the acetone distillate contains nitrous acid, the results will be vitiated owing to the decomposition of the potassium iodid contained in the decinormal iodin solution. The distillate will, however, never contain nitrous acid unless the urine has undergone bacterial decomposition. Since reliable information is not sought from an analysis of badly decomposed urine, the presence of nitrous acid is an exceedingly improbable source of error. It may, if present, be detected with a little starch-potassium-iodid solution, and eliminated by adding a little urea to the distillate. I have applied this reliable test to the distillate hundreds of times, but have abandoned it as a routine procedure, as in no instance has nitrous acid been found present.

---

[8] In case the urine contains more than 98 mgm. of acetone in 100 c.c. no free iodin will be liberated on adding the acid. This will not often be the case, however, but should it occur it will be necessary to add an additional 10 c.c. of the iodin solution; again, to make alkaline with about 15 c.c. of the sodium hydroxid solution, allow it to stand about fifteen minutes, as before. This procedure could always be obviated by adding 25 c.c. of the iodin solution in the first place. This should be done when acetone is known or suspected to be present in greatly increased quantities.

[9] Made by adding 1 gram of starch to 100 c.c. of 0.5 per cent. sodium hydroxid in distilled water, heating to the boiling point and cooling in running water. This solution will keep for several months

---

CARCINOMA OF THE SIGMOID WITH METASTASIS IN THE LEFT ILIUM

REPORT OF A CASE

BENJAMIN G. BENSON, M.D.
AND
LOUIS RASSIEUR, M.D.
Instructor in Surgery in the Medical Department of St. Louis University
ST. LOUIS, MO.

When reading the recent literature on carcinoma of the sigmoid, we were impressed by the fact that the *most important question is not so much one of operative technic, but one of early diagnosis*, the point dwelt on by Armstrong and by Bloodgood.

The classic symptoms of this disease are all signs of a late stage, namely, obstruction of the bowels or its results. There is a dearth of signs which indicate this condition in its incipiency. Sigmoid carcinoma gives a good prognosis only when operated on in its earliest stage. This paucity of signs in the early stage justifies a more frequent employment of explorative laparotomy even when the symptoms are insufficient to establish an early diagnosis. The so-called pathognomonic symptoms of this disease are in reality manifestations of a late stage at which we can seldom expect a cure by operation.

A history of the following case, bearing on the above, seems to us of sufficient importance to be recorded in the surgical literature. Dr. Benson reports the following:

History.—On June 18, 1908, early in the morning, Mrs. K., aged 42 years, consulted him, stating that she had been awakened the previous night by severe pains in the abdomen. After a short interval she felt nauseated and began to vomit. As far as he could learn, the vomitus consisted of some particles of food and slime together with a small quantity of a yellowish fluid. She added that there had been no bowel movement for the past three or four days. Pulse was somewhat accelerated and the temperature normal. Consent to a more thorough examination could not be obtained at this time. The patient merely wanted something to relieve her pain, believing her symptoms trivial and temporary. For the vomiting Dr. Benson prescribed hourly doses of 1/10 grain of calomel, small pieces of ice, and rest in bed. In addition enemas of soapsuds were given and all food and drink was withheld. The same afternoon the pain became more severe. The vomiting had almost ceased. Repeated enemas of soap-suds were ineffective. Patient stated that she had been previously healthy. Her family history was negative. She had been married twenty years and had never been pregnant.

Examination.—The patient was fairly well nourished; her color was good. Cachexia was noticeably absent. The thoracic viscera were examined in detail. All were seemingly normal. The abdominal findings were: Liver and spleen were not enlarged. There was very little distention. No tumor could be found. Bimanual examination through vagina and through rectum revealed nothing abnormal. An examination of the urine proved negative. From the above findings, obstructions which form enlargements could be eliminated. The picture was that of a chronic obstruction in the distal portion of the colon, the sigmoid.

The following day the patient's bowels moved. An emulsion of castor oil (Fenner's formula) had been given. The stools were not saved for the physician's inspection. The patient ceased visiting him. On June 27, 1908, patient returned and said that her bowels had not moved for three days. Magnesium sulphate was given. At 2 a. m. June 28, 1908, the doctor was called to see her in an acute attack. It was similar to the first but more severe. The patient's abdomen was more distended. Her temperature was 99.8 F. The abdominal pain was more severe. Pulse was 84. Morphin sulphate was given hypodermically to allay the pain. The enemas and other directions were the same as during the first attack. Dr. Louis Rassieur saw the case with Dr. Benson a few hours later. He concurred in the diagnosis of a bowel obstruction and that it was probably due to sigmoid cancer. Patient was sent to the hospital June 29, 1908. Here the sigmoidoscope (Strauss) was introduced. At a depth of 18 cm. a seeming narrowing of the lumen could be seen. During the examination a little liquid feces passed the point of supposed stricture. The following day this procedure was repeated. The sigmoidoscope was introduced for 24 cm. and no stricture could be seen.

First Operation.—A laparotomy was made by Dr. Rassieur on July 2, 1908. An incision was made in the median line below the umbilicus. There was no ascites. The sigmoid presented a constriction.. It looked as if a ligature had been passed around the intestine. There were no adhesions. About 15 cm. of intestine were excised, including the part of the mesentery which contained several indurated lymph nodes. An end-to-end anastomosis was made. The sutures were of Connell type and of linen. The abdomen was closed without drainage. The constricted mass of the intestine was hard.

The bowels moved two days after the operation and have since been regular. The wound healed by first intention. On the third day after the operation the patient complained of pain along the course of the left external cutaneous and the left ilioinguinal nerves. The patient's general condition improved rapidly, however. The pain steadily increased in severity, notwithstanding the giving of antirheumatic and antineuralgic drugs. In the latter part of September, 1908, the soft parts over the crest of the left ilium seemed to be somewhat enlarged and of a doughy consistency. The bone also seemingly showed a thickening. An *x*-ray picture verified this view. No other metastasis could be found.

Second Operation.—This was made October 19, 1908, to remove the enlargement of the ilium. An incision was made over the crest of the ilium from the posterior superior spinous process of the ilium to the middle of Poupart's ligament. The muscles and fascia were edematous. The peritoneum was not adherent and fell away on division of the muscles. A tumor of the ilium of osteoclastic nature 5 inches by 3¼ inches by 2⅝ inches was removed with bone drill and Gigli saw. An additional rim one-half inch in diameter was removed from the ilium with rongeur forceps. Then the fascia lata and the divided fascia iliaca were again united to the fascia iliaca. A small cigarette drain led to the bone. Portions of external cutaneous and ilioinguinal nerves were excised.

Postoperative History.—The convalescence after the second operation was uneventful up to the middle of February. Until that date the patient was free from pain; there was no recurrence of the tumor; no hernia marked the site of the removed bone, and a slight limp alone hinted at the disturbed relation of the muscles. On March 16, 1909, we learned, the patient again walked with difficulty. She had pains in the affected lower extremity, extending down into the foot, which kept her awake. She presented a tumor on the left iliopectineal eminence, the beginning of which, she said, was insidious about four weeks before. An operation was advised. Owing to circumstances which we could not avoid, the patient was transferred to the care of other physicians.

Description of First Specimen.—The stricture of the sigmoid was so fine as to forbid the passage of the smallest surgical sound. A cup-shaped ulcer was on the distal side of the stricture. Microscopic examination showed the original tumor to be very small. The contraction and cicatrization were seemingly due to secondary inflammation. The specimen was an adenocarcinoma. In some instances the excretory duct of the cancer tubules could be seen emptying in the end of the Lieberkühn glands. There were few glandular metastases showing tubo-alveolar arrangement and round-cell infiltration.

Description of Second Specimen.—The diameters of the metastases in the bone were stated above. The tumor was osteoclastic and originated in the medulla of the crest of the ilium. A smear of the medulla, stained with azur No. 2, showed cancer cells. A hardened section stained with Unna's polychrome methylene blue and Unna Taenzer's elastic stain showed an adenocarcinoma with many figures of indirect cell division and remains of bone.

The first and second *x*-ray pictures showed the tumor, which extended on the inside almost to the brim of the pelvis and on the outside almost to the acetabulum. The third *x*-ray picture showed the remains of the bone and an absence of recurrence. The fourth,made Mar. 20,1909, showed a tumor over left iliopectineal eminence and a questionable shadow on left trochanter. The radiographs were made by Dr. Carman.

In conclusion, we believe the following points of especial interest:

1. Extreme stricture of the sigmoid with such a paucity of clinical signs.
2. A seemingly solitary metastasis and that in the ilium of the same side and apparently none in the usual site.
3. The shortened convalescence after excision of the sigmoid and union without drainage.
4. The value of a second operation to remove a seemingly solitary metastasis, demonstrated by the patient's temporary improvement. We were in hopes that this might even prove a cure.
5. Absence of hernia after removal of so large a portion of the iliac bone.
6. The value of the *x*-ray in the demonstration of bone metastasis.

We wish to add that, after a careful perusal of the literature, not a single case was found in which there was a seeming single metastasis, even in the iliac bone (an accessible field).

2136 Benton Street—316 Metropolitan Building.

Evolution in Purin Metabolism.—According to the studies of H. G. Wells (Trans. Chicago Path. Soc., May 1, 1909), the invertebrates are able to convert adenin into hypoxanthin and guanin into xanthin, showing the presence of the enzymes, adenase and guanase, but the metabolism proceeds no farther. Passing upward in the scale of animal life to the birds and reptiles we find that nitrogen is excreted chiefly in the form of uric acid. Mammals form uric acid only from the purins and have the power of destroying some of the uric acid formed. The enzymes that destroy uric acid seem to be the last formed in development and are possessed by various mammals in varying degrees and in the same animal often show an uneven distribution in the various organs of the body. This uricolytic power is relatively weak in man. Wells cites the observations of Mendel and Mitchell on embryo pigs as illustrating the biologic law that the individual in its development reflects the entire development of the species to which it belongs (*Am. Jour. of Physiol.*, 1907, xx, 97). They found nuclease and adenase at very early stages, but no xantho-oxidase until the fetal pigs had reached a length of 200 mm. or over. In other words, in its earlier stages of development the pig possesses only the same purin enzymes as the invertebrate, while somewhat later it is equipped as the birds and reptiles may be supposed to be; that is, with xantho-oxidase, but without uricolytic enzymes. The uricolytic enzyme is wanting entirely until after birth, when it soon makes its appearance, but in the suckling pig it is still not so active or abundant as in the adult animal. This enzyme is, therefore, the last of the entire series of purin enzymes which is acquired by the developing individual, just as it seems to be the last to be acquired in the evolution of the animal kingdom.

Therapeutics

PNEUMONIA AND ITS COMPLICATIONS

Since the discovery of the tubercle bacilli by Robert Koch, in 1882, much has been learned in regard to the rôle of micro-organisms in the pathology of disease. These discoveries have been supplemented by and have rendered possible the introduction of antiserums and vaccines in the treatment of some diseases. Of these the antiserum, or, as it has been commonly called, the autitoxin of diphtheria, is the most successful one and the one best known. Diphtheria is recognized as a general toxemia produced by a local infection.

Acute pneumonia, on the other hand, is practically always a pneumococcus septicemia. The pneumococcus (the *Diplococcus pneumoniæ*) which Fraenkel discovered in 1883 is the cause of true pneumonia. This organism is not confined to the lungs or to locally infected areas, but may be found in the blood. It has been shown that antipneumococcus serum has no bactericidal effect on living pneumococci, and that different strains of pneumococci are not affected in the same way by different vaccines; so that animals immunized against one strain are not necessarily protected against others. Hence it has been found desirable to prepare the vaccine from cultures made from the pneumococcus infecting the individual patient. When this is impracticable, a vaccine from a particularly virulent strain may be used.

"The bacterial vaccine consists of the specific organism isolated in pure culture and, after destruction by heat, suspended in normal salt solution."—(Floyd and Worthington, *Boston Medical and Surgical Journal*, Jan. 2, 1908). In acute pneumonia, a pure culture may generally be obtained from the "rusty" pneumonic sputum.

Dr. A. Butler Harris, of London, has recently published (*Brit. Med. Jour.*, June 26, 1909) a report of his investigations and observations on the vaccine treatment of pneumonia. Harris grows the pneumococci obtained from the patient on agar-agar which has been smeared with a thin layer of blood drawn from the finger. When the patient's sputum is not available, he advises the withdrawal of some of the patient's blood from the median basilic vein, and generally thus obtains enough pneumococci for the culture. His technic is well described in his article.

It has been found that the pneumococcus is present at different times, somewhere in the air passages of perhaps 50 per cent. of all individuals, especially during the winter. The most characteristic location for the manifestation of its pathologic action is in the lungs, where the inflammation that it causes usually runs an acute and rather short course. By no means infrequently, however, cases occur in which the lung lesion does not resolve and the pneumonic process continues and the pneumococcus persists, or the pneumococcus has infected other regions which do not tend to heal, such as the pleura, peritoneum, endocardium, joints, veins, and middle ear. These are typical instances in which pneumococcus vaccine should be used.

Harris reports eleven cases of various forms of pneumococcic infection. Three patients died early from failure of the heart. One man, aged 36, died on the fifth day, after having received inoculations on the third, fourth and fifth days. A man, aged 58, was taken with recurring rigors and consolidation of the base of the left lung. He received an inoculation the same day at 6 p. m., and the next morning at 10:30 a. m. was convalescent. The other seven cases were of a chronic character and included delayed pulmonary resolution, empyema, asthma, and joint infection. All were benefited by the inoculations.

The dosage varies from ten to twenty millions of dead pneumococci in children of 3 or 4 years of age to from thirty to eighty millions for adults. The dose may be repeated every twenty-four hours if necessary, or every third or fourth day.

Harris summarizes his conclusions as follows: "1. Successful inoculation for pneumonia is possible. 2. Inoculation does no harm. 3. A vaccine from one or a number of virulent strains should be used. 4. It should be introduced as early as possible. 5. The estimation of the opsonic index is not necessary. 6. The observation of the temperature and physical signs is in pneumonia a sufficient guide in gaging the repetition of the dose."

We can but agree with his final proposition, viz.: that "infections of the lung by the pneumococcus which fail to resolve after an acute pneumonia, as well as pneumococcus infections of other areas, ought certainly to be treated with a pneumococcus vaccine." An autovaccine should be preferred, and the prospect of successful treatment seems good.

DIET IN CHRONIC DISEASES

This is the age of "diets" and fads in diets. Whether the well eat too much or too little, too frequently or too infrequently, too much protein or too little protein, too much carbohydrate or too little carbohydrate, is a subject too large and too varied to discuss here. It is important, however, and necessary to analyze carefully the food and digestive power of a patient who is suffering from chronic disease or disability.

It is certain that unnecessary amounts of or ill-chosen food can cause fermentation and even putrefaction in the intestines. If actual autoinfection is not caused, certainly nervous and circulatory irritants may be absorbed from such abnormal intestinal fluids. These irritants may create disease, and certainly will augment disease that is present.

Dr. William H. Porter, of New York, writes a thoughtful paper (*Post-Graduate*, June, 1909) on the subject of this article, and specifically presents a diet that he says will minimize intestinal indigestion. He calls to our mind the subdivisions of food as:

1. Inorganic, including water and salts.
2. Cellulose, starch, and sugar. } Heat-producing
3. Fats of all kinds. } substances.
4. Proteins.
5. Protein-like compounds, to which an atom of iron and phosphorus is attached in its synthetic formation. These may be distinguished as hemoglobin-yielding and lecithin-yielding substances.

The last two classes are the construction tissue building protein compounds.

Each of these five classes must be represented in the daily dietary in order to insure the most satisfactory nutritive results, and at the same time caution must be exercised that the total amount of food be kept within the "oxygenating capacity" of the system.

The five classes of food enumerated above are contained in both animal and vegetable foods. Accordingly, it is not surprising that there have been advocates of an exclusive vegetable diet; and, on the other hand, that it has been proposed to exclude articles of vegetable origin more or less completely from the diet, food of animal origin only being advised.

In order to correlate an adequate amount of the different classes of food to fulfill the demands of the body for heat-producing, tissue-building, and hemoglobin-yielding, [illegible] substances with the "oxygenating [illegible]y, it has been found that a mixed diet, comprising both animal and vegetable substances, is most advantageous.

In health, Nature allows a considerable latitude between the amount of food which can be taken and the "oxygenating capacity" of the body. But in disease conditions are changed, the "oxygenating capacity" is lessened, and care must be taken not to overtax it by excess in ingestion of food beyond the body demands.

With the above generalizations Porter suggests the following as an ideal mixed diet for patients who are suffering from chronic disease:

"For breakfast: Two eggs, eight ounces of milk, two ounces of wheat bread and butter.

"For the mid-day meal: From one-quarter to one-half pound of beefsteak, eight ounces of milk, three ounces of wheat bread and butter.

"For the night meal: From one-quarter to one-half pound of beefsteak, eight ounces of milk, two ounces of bread and butter.

"At bedtime: Eight ounces of milk."

Beefsteak is used as a representation of the meats because it is most easily and perfectly digested; for it may be substituted lamb, mutton, veal, fish, poultry, and game.

If it is desired to enlarge this diet by substituting a vegetable in place of a part of one of the articles enumerated, string beans, green peas, lima beans, spinach, lettuce, asparagus or cauliflower, well cooked, may be permitted.

Porter enumerates as foodstuffs to be avoided "all fruits, either cooked or raw; all cereals and breakfast foods, nuts, sweets and pastry of all kinds, potatoes in all forms, onions, tomatoes, turnips, parsnips, carrots, celery, radishes, cabbage, egg-plant and oyster-plant, corn, etc.; pork in all forms, except as before stated, rich gravies, and all forms of soups." Most of the above articles he finds difficult of digestion and promoters of fermentation and putrefaction in the alimentary canal. Potatoes are easily and rapidly digested and consequently the "oxygenating capacity" of the body is overtaxed, so that the protein constituents of the food are not oxidized and assimilated, as they must be if a perfect state of health is to be maintained.

Finally, Porter sums up his conclusions as follows:

Animal food is more nearly a perfect nutritive than vegetable food.

Animal food is more easily digested and assimilated than vegetable, and therefore more economical to the system.

A perfect or ideal diet should comprise both animal and vegetable food.

The diet, consisting of the exact proper combination of animal and vegetable food, found to be the most perfect for the individual patient, combined with whatever medicinal and physical treatment deemed advisable, will often produce "marvelous" improvement in the patient.

No Milk in Summer Diarrhea.—In the treatment of babies affected with the infectious diarrheas of the summer season, milk has no place. Whether we are dealing with a milk infection or not, and usually we are, milk will still furnish a splendid culture medium for the bacteria still inhabiting the disturbed gastrointestinal tract.—J. H. McKee, in *Monthly Cyclopedia and Medical Bulletin.*

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1909," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 1643)

SODIUM PERBORATE.—(See SECOND SUPPLEMENT to N. N. R., 1909.) Proprietary Preparation:

PEROGEN BATH—Oxygen Bath Salts. Perogen.—Perogen bath is a preparation consisting of a catalyzer and sodium perborate capable of yielding 10 per cent. of oxygen, the two substances being wrapped separately.

The catalyzer is a light yellow odorless powder, and is made by a method which is the subject of a patent application now pending. The oxygen contents may be determined by any of the well-known methods.

Actions and Uses.—The catalyzer is a medicinally indifferent substance. When the two substances are mixed with water the catalyzer causes the liberation of the available oxygen of the sodium perborate. The oxygen bath thus obtained is said usually to reduce blood pressure and the pulse rate to a much greater extent than the ordinary bath. It is claimed to have marked tranquilizing and somnifacient effects. It is said to be useful in cardiac affections with high vascular tension and excitement, neuroses, insomnia, chronic nephritis, and skin diseases in which hydrogen dioxide is indicated.

Dosage.—One bath daily up to 24 or 48, with occasional intermissions.

Manufactured by Morgenstern & Co., 59 Maiden Lane, New York. U. S. patent and trademark applied for.

METHYL CHLORIDE—Methylis Chloridum.—Methyl chloride, CH_3Cl, is the methyl ester of hydrochloric acid. It occurs, in the compressed state, as a colorless liquid, having an ethereal odor, and a sweet taste.

Methyl chloride is insoluble in water, more readily in alcohol, freely in ether and chloroform, and also in acetic acid. It should be neutral to litmus paper. At about —25° C. (—13° F.) it has a specific gravity of 0.991, and boils at about —21° C. (—5.8° F.). It burns in air with a greenish flame, though it is not highly inflammable. The neutral solution is not precipitated by solution of silver nitrate, nor is there any reaction with potassium iodide and starch paste. In the liquid condition it is a powerful refrigerating agent. At very low temperatures it forms with water a hydrate, $CH_3Cl,9H_2O$. It should not react alkaline to litmus (absence of ammonia and methylated ammonia—methylamine). It should not immediately form a precipitate with silver nitrate. On evaporating it should leave no residue and emit no odor of methylamine.

Action and Uses.—By its evaporation a temperature of —23° (—9.4° F.) is produced, while if evaporation be accelerated by means of a current of air a temperature of —55° (—67°F.) may easily be reached. On account of this property it is used as a local anesthetic in the form of a spray, but its use requires caution, since it is apt to produce blisters. The diluted vapor is said to be non-poisonous. Methyl chloride is said to be an efficient general anesthetic, which has practically no influence on the circulation, but fails to produce complete muscular relaxation. It is used as a general anesthetic mixed with ethyl chloride and ethyl bromide.

Dosage.—When sprayed on the skin the part should be partly protected by a thin layer of cotton wool. When used locally cotton wool soaked in liquid methyl chloride may be applied to the skin over the painful area, but care should be taken that blisters are not formed. In order to avoid this a mixture with ethyl chloride has been recommended.

MEAT EXTRACTS AND BEEF JUICES

While the extreme importance of carefully planned dieting of patients has been recognized for centuries, it is only in comparatively recent years that this subject has been studied by methods as precise and logical as those that have been devoted to other great problems in medicine. At present, however, we have means of learning accurately many of the most fundamental facts regarding the nutritive value and the composition of foods. Therefore, in the increasingly successful struggle now in progress to put therapeutic methods on the same scientific plane as diagnostic methods, it is our duty to scrutinize foods—especially those that are particularly recommended for the invalid or sick—in the same judicial way that we do drugs and other measures. That is, we must form opinions, not on the basis of vague impressions of the apparent results of the use of foods, and especially not on the basis of statements of manufacturers or other interested parties, but primarily in accordance with their composition and the food value that can be determined from this. Investigations like the report of the Council on Pharmacy and Chemistry on medicinal foods, Winton's and Fetterolf's analyses of diabetic and similar foods, and other disinterested studies, already have shown us that with foods, as with drugs, we can find a limited number of proprietary articles that are what they are advertised to be, but unfortunately many more that are not. In some instances the facts are startling as compared with claims made—startling because these preparations have been widely employed in serious conditions, when misapprehension as to the nutritive value of the food used is likely to be highly dangerous.

In many respects the most astonishing report on such preparations is that which appears in the Department of Pharmacology in this issue, dealing with substances purporting to be beef-juice or meat-juice. With many physicians—and with many of the laity—the names of some of the preparations that the report deals with have been names to conjure with. Anything that lays claim to being the best part of good red beef sounds so nourishing that the name itself makes people feel fed. It is humiliating, but most enlightening, to physicians who have used such preparations to learn that these are not beef-juice or meat-juice at all. It is even more important to note the surprisingly low calorific value. Not only have these preparations been sold under names that have given them an exaggerated value, but their value under any name is so slight that we cannot escape the conviction that many persons must have been simply starved while, with firm faith in the reputed value of the extracts, the prostration and emaciation have been attributed to the disease instead of to the lack of nourishment in the "food." All the advertising arguments conceivable, all the specious claims that can be advanced, cannot change the fact that to give a patient a microscopic fraction of the amount of energy that he necessarily expends is starvation. It is really appalling to see the difference between the claims and the facts. One manufacturer claims that a tablespoonful of his preparation equals in value one hundred grams of raw meat; as a matter of fact it contains a little under four calories to the tablespoonful, while one hundred grams of meat, even when very lean, contain 125 or more calories. Another preparation, according to the advertisements, contains in two ounces the concentrated juice of four pounds of the best beef; actually it appears to contain absolutely no beef-juice and is merely a thin meat-extract.

Doubtless the manufacturers will argue that, no matter what analyses show, the extensive sale of their preparations proves their value; doubtless, too, there are physicians who will be willing to assert that they have derived good results from the use of these products. Scientifically considered, such arguments are of the *post hoc, ergo propter hoc* variety. Patients who have recovered when given preparations that are nutritively worthless have recovered in spite of, and not because of, the "food" administered—or because semistarvation was indicated in these cases. Not only laymen, but even some physicians, have not yet divorced themselves from those medieval methods of thought which credit any artificial means of treating disease, be it ever so absurd, with results that are more rationally attributable to the *vis medicatrix naturæ*. This fallacy is nowhere more evident than in the therapeutics of so-called medicinal foods. Verily, strange therapeutic idols have been worshiped by those who have used such preparations, but the day of false gods is drawing to its close. With further contributions like the one which appears in this issue, we may hope that vagueness and uncertainty in dietetics will give way to rationality and precision.

THE PATHOGENESIS OF SPONTANEOUS CEREBRAL HEMORRHAGE

Since the classical article of Charcot and Bouchard in 1868 it has been common knowledge that cerebral hemorrhage is associated with the presence of minute aneurisms in the smaller, intracerebral arteries, and that the hemorrhage is presumably the result of the giving way of these aneurismal dilatations. In sixty cases of cerebral apoplexy these authors found miliary aneurisms, from two to hundreds in each brain, arising on arteries of a diameter of 0.03 to 0.25 millimeter, and established by their research the significance of the aneurisms in the pathogenesis of cerebral hemorrhage. Earlier investigations, however, had already pointed out the existence of these aneurisms, Morgagni himself in 1761 having stated that rupture of the cerebral arteries was a consequence of their widening, whereby the walls became thinned; but it was not until 1859 that the actual source of a hemorrhagic extravasation in the brain was detected in a ruptured miliary aneurism by Gull. The reason for this tendency of the small cerebral arteries to undergo aneurismal dilatation and rupture seems to be twofold: In the first place, these vessels lack a firm external support because of the softness of the brain tissue and the delicate structure of the adventitia surrounding them; in the second place, as Mendel demonstrated in 1891, the blood pressure in the arteries of the basal ganglia is greater than in the other parts of the brain.

Just what changes take place in the vessels during the formation of the aneurisms, and the relative importance of aneurism formation and rupture of undilated vessels as the source of cerebral hemorrhages, are matters concerning which there has not been agreement, and there is also dispute as to whether the dilatations are true or false aneurisms. In an excellent paper, from which the preceding historical review has been abstracted, A. G. Ellis[1] reports an extensive reinvestigation of these old problems by modern methods. In thirty-one cases of cerebral hemorrhage he found macroscopic aneurisms, varying in size from 0.5 to 4 millimeters in diameter, and in four cases ruptured aneurismal sacs were found. Histologic study of the vessels and aneurisms showed that the primary lesion is in the intima, the elastica being primarily at fault as in arteriosclerosis of vessels other than those of the brain. The damaged intima frequently ruptures, and blood forces its way between the coats of the vessel, producing dissecting aneurisms which later, through destruction of the remnants of the vessel wall still surrounding the blood, become converted into false aneurisms bounded by fibrin and altered brain tissue. False aneurisms are also formed by rupture of a vessel after degeneration of media and adventitia has followed the primary degeneration of the intima. In any case, the aneurismal dilatations found on the cerebral vessels are false aneurisms, and not true aneurisms surrounded by one or more layers of the vessel wall; and also the primary vascular lesions are intimal rather than in the media or adventitia as has been contended.

Ellis believes that cerebral hemorrhage does not always come from rupture of aneurisms, for sometimes the sclerosed vessels are found to have ruptured directly without previous dilatation. It is probable, however, that the more usual cause of a spontaneous cerebral hemorrhage is rupture of a false aneurism; and it also seems that the large hemorrhages with great destruction of brain tissue are usually from this cause, since in this way the entire current of blood may suddenly enter the brain substance.

HEROES, THOUGH THEY DID ONLY THEIR DUTY

From the Illinois coal-fields comes a story of horror and disaster. In the lower levels of the St. Paul mine at Cherry nearly four hundred miners were at work. An alarm of fire was given and they rushed for the shaft, only to find their way to safety barred by a wall of flames. At the smoking pit mouth above, the mine foreman called for volunteers to go down into the burning mine and bring out the survivors. Fourteen men stepped forward, at their head the company's physician, Dr. Lyston D. Howe. Of this brave band, twelve lost their lives trying to save their comrades. Dr. Howe and one miner alone escaped. Let the newspaper correspondent tell the rest of the story:

"Standing out above all the rest is the story of Dr. L. D. Howe, the St. Paul Company's physician, who was the first rescuer to enter the mine. Seven times before the other rescuers began to go down into the burning shaft, this young physician went down alone into the flaming pit and each time he brought to the surface his quota of saved. Twenty-five miners owe their lives to him. To-day his hands are badly burned, but he shows no other scars. When asked this afternoon to describe his experiences, he merely shrugged his broad shoulders and said, 'I could not have done anything else than I did. It is not worth talking about. Besides, I am too busy to talk to-day.'"

The following item appears in this week's letter from our London correspondent: "In the early morning an explosion occurred in the Darran Colliery, South Wales, before the workers on the night shift had left. The ordinary approach to the mine was completely blocked, and the only access was through the shaft of another pit four miles away. A relief party, accompanied by Dr. Turner, the colliery surgeon, descended into the pit and endeavored to reach the other shaft. One after another they were overcome by the choke-damp and five died. The physician had a narrow escape. He repeatedly risked his life in leading the relief party and at last collapsed. His companions endeavored to rescue him, but were so overcome by the choke-damp that they had to abandon him. After a time they were able to return and found him lying in the roadway, still alive. He was carried to a place of safety and oxygen was administered. He was then taken in a comatose state to the Cardiff Infirmary."

All honor to these brave physicians who risked their lives to save others. While they did only their duty, they are heroes none the less. No better example of the true physician could be found than the young mine surgeon who only did his duty and was too busy next day to talk about it.

THE ENZYME TREATMENT OF CANCER

The treatment of cancer by injection of preparations containing pancreatic enzymes, as proposed by Dr. John Beard, of Edinburgh, about four years ago, excited so much interest and comment at the outset that it is hardly necessary to recount its principles or objects. It will be remembered that the treatment was based on an embryologic hypothesis as to the part played by the pancreas in controlling cell growth (a hypothesis which, to say the least, has not been generally accepted by embryologists), and all will recall the sensational manner in which the new treatment was exploited in lay journals. To anyone acquainted with the biology of cancer cells and the properties of enzymes the entire proposition appeared unpromising, but none the less there were not a few practitioners who seemed to see good results accruing from the treatment, and some were carried to extremes of enthusiasm. Taking an unprejudiced view of the situation, however, it seemed possible that the trypsin and amylopsin preparations might have some local effects equivalent to those of mild escharotics, and without their disadvantages, but any specific curative effect, such as was anticipated by Beard, that should lead to "the conquest of cancer" was not to be expected or hoped for.

Four years' experience with the treatment has given opportunity for its real value to be established and for the permanence of the results which at first aroused enthusiasm to be finally decided. More than one hundred articles have been written on the subject, and of three thousand physicians interrogated by the Committee on Scientific Research of the New York Skin and Cancer Hospital, about five hundred reported that they had tried the new method. The originator and advocates of the treatment, therefore, cannot complain of lack of investigation and attention on the part of the profession, and if the unfavorable verdict which has generally been reached is ascribed to lack of experience, care or thoroughness by the users, this criticism cannot well be applied to the report recently published by Dr. W. S. Bainbridge, the secretary of the committee mentioned above.[1] In this report are detailed the results of the treatment of cancer in one hundred cases by the method advocated by Beard, carried out in its full details, with careful study not only of the patients' general condition, but also of the blood, urine, and the tumors themselves. The treatment appears to have been given a most impartial and thorough trial, so that there seems little room to take exception to the conclusion reached, namely, that "the enzyme treatment does not cure cancer." It is found that the local treatment of the ulcerating surface and the general régime advocated by Beard have a favorable influence on the local and general condition of the patient, but there is nothing in the nature of a specific cure of the cancer growth, or even of the prevention of metastasis or recurrence; while at times the injection of trypsin may cause dangerous injury, and often it is unbearably painful. Perhaps the most important positive result is described in the author's retrospect in the following words: "Looking back on the work of the last three years, the most important lesson to be drawn from the enzyme treatment of cancer is that the patient is a human being who, while suffering from cancer, it is true, may at the same time be the subject of any of the other ills to which flesh is heir, and who doubly deserves to be treated with all the careful scientific attention which modern medicine and surgery command. By building up the nutrition, aiding the impaired function of elimination, treating complications, giving the patient a better mental as well as physical atmosphere—in other words, treating the patient and not the 'cancer case'—suffering can be wonderfully ameliorated and life, in many instances, prolonged in comparative comfort for months and even years." But this is a long way from a specific cure—from "the conquest of cancer"—more's the pity.

HYDROTHERAPY

While it cannot be said that qualified medical men ignore the therapeutic use of water (unless here and there some isolated individual, like one who a few years ago objected to the practice of bathing as insanitary), it can safely be admitted that most physicians do not habitually employ hydrotherapy in many ways in which it might be beneficial to their patients. Many difficulties stand in the way as regards the mass of the profession. A complete hydrotherapeutic outfit is beyond the reach of the average physician, and the means for using the simple domestic methods are not always available in the homes of the poor. The exploiters of hydrotherapeutic methods in our cities, and even in some of the so-called water-cures, often have not the full confidence of the profession. In some of the best hydrotherapeutic establishments one cannot always be sure that the cure is applied in a thoroughly scientific instead of an empirical, routine way. The associations of special therapeutic institutions are not always the best, and sometimes there is a justified suspicion of quackery in the mind of the physician who might otherwise contemplate sending patients there. There are not many places to which physicians can send a patient and assure him that he will receive the scientific aid that he requires and which he has a right to expect. While some resorts can be conscientiously recommended, they are often beyond the means of a large class of worthy people. Hence the need, especially in cities, of institutions where a physician can prescribe and in a measure oversee the treatment of his patients, feeling sure that nothing will be done for which he cannot himself assume the responsibility. Even in the city of Boston there was not, up to within a very few years, according to Dr. Pratt's article in the present issue, a single place where one could have a therapeutic douche, a scientific wet-sheet rub, or a carbon dioxid bath given by a man or woman familiar with the proper hydrotherapeutic methods. The history given by Dr. Pratt of the foundation, equipment, etc., of the Boston Medical Baths illustrates what might be done in other cities, where similar institutions could be made of great value, not only for the scientific treatment of persons who cannot for financial or business reasons avail themselves of the well-known establishments in this country and abroad, but also for the educational effect on the public and even on the medical profession. It would afford an opportunity for the individual treatment needed under the direction of the physician who best knows the case and who has the confidence of the patient. There is no conscientious therapeutist who does not wish to give his patients every possible opportunity to use all the means that may benefit them. The application of water in its various forms and in the ways approved by experience is one of these.

THE VALUE OF NASAL EXAMINATION IN THE DIAGNOSIS OF LEPROSY

Several years ago, Sticker advanced the claim that the initial lesion in leprosy is situated on the septum of the nose. Were this the case, the detection of incipient cases of leprosy would become a comparatively easy matter. Impressed with the possible practical value of nasal examination in the diagnosis of leprosy, Brinckerhoff and Moore[1] in Hawaii determined to gather further data in regard to the question of this alleged initial lesion of leprosy. Inasmuch as most of the previous investigators based their conclusions on results obtained from the examination of patients in whom leprosy was relatively advanced and in whom it would be exceedingly difficult if not impossible to determine the primary lesion, Brinckerhoff and Moore examined not only lepers in the early stages for primary lesion on the nasal septum, but especially persons not known to be lepers but among whom it was reasonable to expect that a considerable number of as yet unrecognized instances of the disease would exist. Certain institutions in Hawaii offer exceptionally favorable opportunities for the discovery of cases of leprosy in the earliest stages if the first symptom of the disease actually is an ulcer on the nasal septum. Without discussion of details, suffice it to say that the Hawaiian investigators carefully examined the nasal septum and nasal secretion of 407 suitable persons without finding as many cases of leprosy as expected from the statistical data and on the assumption that this method would be of distinct value in the diagnosis of the disease in its incipiency. Hence they feel decidedly doubtful as to the value of nasal examination for the early diagnosis in all cases of leprosy, and in this conclusion they are supported by the results of their examinations of known cases of leprosy. In four of five cases of incipient leprosy, inspection of the nasal septum and bacteriologic examination of the nasal secretion failed to detect any evidence of leprosy either in the form of actual lesion or in the presence of lepra bacilli in the secretion. In the fifth case they found a single large mononuclear cell containing unmistakable lepra bacilli. On the other hand, in cases of considerable duration they found septal lesions and bacilli in the secretions to be the rule. In one case, in a dispensary patient, in which full history and physical examination could not be secured, a considerable number of lepra bacilli were present in the nasal secretion—an example of the value of routine examination of the nose in detection of dangerous cases of leprosy in a clinic frequented by races with a high incidence of this disease. Brinckerhoff and Moore consequently assign a certain value to nasal examination in the detection of leprosy, even if it does not reveal all cases of the disease, as would be expected if the initial lesion, as once claimed, occurs on the septum of the nose.

Medical News

ILLINOIS

Money for Hospital.—Evanston Hospital has received an anonymous gift of $25,000. The money has been applied to the endowment fund, which now amounts to $86,000.

No Provision for Pay of Experts.—The Illinois Occupational Disease Commission, which had made arrangements for an exhaustive study of the conditions in the factories of Illinois, finds its hands tied because the bill enacted by the state legislature, which provides for an appropriation of $15,000, fails to specify expert and medical aid in its list of the purposes for which the money may be used.

Personal.—Dr. Arthur C. McIntyre and family, Troy Grove, have returned from Europe.——Dr. Edwin J. Gause, Unity, county commissioner-elect of Alexander county, took the oath of office November 5.——Dr. Charles B. Fry, one of the oldest practitioners of Mattoon and local surgeon for many years of the Illinois Central and Big Four railroads, announces that he will give up the active practice of his profession.

Elections.—At the annual meeting of the Southern Illinois Medical Society, held in East St. Louis, November 5, the following officers were elected: President, Dr. Oscar B. Ormsby, Murphysboro; vice-presidents, Drs. Edward W. Fiegenbaum, Edwardsville, and Andrew Hall, Mount Vernon; secretary, Dr. Charles W. Lilie, East St. Louis; assistant secretary, Dr. Alonzo B. Capel, Shawneetown, and treasurer, Dr. H. E. Telford, Centralia. The next meeting is to be held in Centralia.——At the eighty-ninth semi-annual meeting of the Fox River Valley Medical Society, held in Aurora, November 9, Dr. Edward H. Abbott, Elgin, was elected president; Dr. C. H. Evans, Aurora, vice-president, and Dr. William H. Schwingel, Aurora, secretary-treasurer.——The Kewanee Physicians' Club, at its annual meeting, November 4, elected the following officers: President, Dr. Peter J. McDermott; vice-president, Dr. H. Nelson Heflin, and secretary-treasurer, Dr. Gideon H. Hoffman.

Chicago

Physicians Protest.—An ordinance prohibits vehicles from remaining on downtown streets without attendants for more than an hour, in order to avoid more congestion of already crowded streets. The council of the Chicago Medical Society, at its meeting, November 9, protested against the law. The physicians want the right to leave automobiles on the street while they are in their offices.

Out-Door School.—A plea for the establishment of a permanent large outdoor school for tuberculous children is made in the report issued November 11 by the Chicago Tuberculosis Institute. Great good is predicted from the out-door school which is to be held on the roof of the Mary Crane Nursery, Ewing street, by the United Charities, supported by the trustees of the Elizabeth McCormack fund.

Antitoxin.—The Memorial Institute and the Chicago druggists, with the assistance of the Department of Health, have entered into arrangements whereby the retail price of diphtheria antitoxin, after November 15, will be, 1,000 units, 60 cents; 3,000 units, $1.10, and 5,000 units $1.50. The previous prices were, respectively, $2, $5, and $7.50. The department urges those able to pay these reasonable prices to do so and to leave the state supply of free antitoxin for poor people who are unable to pay anything for it.

MARYLAND

Memorials.—In the improvements now being made at the Hospital for the Women of Maryland, Baltimore, there will be memorials to Drs. William T. Howard, H. P. C. Wilson and J. E. Atkinson, all of whom were formerly members of the staff, and the two first, founders of the institution.

Loving-Cup Given.—The surgical staff of the Baltimore Eye, Ear and Throat Charity Hospital recently gave a dinner in honor of Dr. Samuel Theobald, one of the founders of the hospital, and a member of the staff since 1882. A loving-cup was presented Dr. Theobald by Hon. Charles J. Bonaparte of the board of managers.

Personal.—Dr. Charles H. Rose, Cordova, has been elected a member of the house of delegates.——Dr. Joshua W. Hering, Westminster, comptroller of the state, was given the honorary degree of LL.D. on academy day at the University of Maryland, November 11.——Dr. Frederick H. Baetjer has been appointed associate in actinography, Dr. H. C. Thatcher assistant to Professor Thayer, and Dr. J. T. Sample assistant to Professor Barker, in Johns Hopkins Hospital.

Hope to Abolish Cocain Evil.—Baltimore feels that it has provided a really effective weapon in its endeavor to abolish the cocain evil; this has been done by the Swan ordinance, passed by the city council, the legality of which was upheld by the Maryland Court of Appeals, at Annapolis, November 12. It is said that the dealers in cocain have been making 200 per cent. profit. Hitherto these individuals have had an option of paying a fine or imprisonment; hereafter imprisonment is to be required and, further, even to have the drug in one's possession, unless on prescription of a regular physician, is to be evidence of guilt.

MASSACHUSETTS

Physicians' Building in Worcester.—Plans are being prepared for a twelve-story office building in the center of Worcester to cost $500,000 to be devoted to the use of physicians, dentists and druggists.

Personal.—Dr. Florence A. Sullivan has been elected a member of the Haverhill Board of Health.——Dr. Wilder Tileston, Boston, has been appointed assistant professor of medicine in Yale Medical School and has moved to New Haven.——Dr. George B. Sargent has been reelected secretary-treasurer of the Lawrence Medical Club.——At the annual meeting of the Massachusetts Charitable Eye and Ear Infirmary, Boston, Dr. George B. Shattuck was elected president.——Dr. Ephraim Cutter, West Falmouth, writes that he has been appointed delegate to the 1910 convention for the Revision of the U. S. Pharmacopeia. This reminds him that it will be fifty years since he went before.

NEW YORK

New York City

Gift to Lawrence Hospital.—This institution, at Bronxville, was erected by W. V. Lawrence at a cost of $125,000 and opened last June. Mr. Lawrence has now given an additional $150,000, $50,000 of which is for the home for nurses, and $100,000 for an endowment fund for current expenses.

Montefiore Home Will Move.—At the annual meeting of the trustees of this institution it was announced that the home would soon be moved to a more favorable site up town, the present quarters not being large enough. The treasurer's report showed expenditures of $180,000 during the last year and donations of about the same amount.

Hudson-Fulton Accidents.—Reports received by the Public Service Commission on the local transportation service during the crowded period of the Hudson-Fulton celebration show that there were no fatal accidents. It is estimated that the elevated and surface cars carried nearly six millions a day during that time without a single fatal accident.

Gift to College.—William D. Sloane, who has already done much for the College of Physicians and Surgeons, has given $150.000 which is to be used for the erection of a seven-story addition to the Sloane Maternity Hospital. The new building will enable the student to receive practical instruction in all phases of obstetrics and gynecology in the same building.

Personal.—In recognition of the services rendered the Roman Catholic Church by his writings and lectures, Dr. James J. Walsh has had the decoration of St. Gregory conferred on him by Pope Pius X.——Dr. A. S. Dair, while racing, lost control of his motor cycle, and was thrown down an embankment, sustaining severe injuries.——Dr. Carlos F. MacDonald, while returning from New York to his sanitarium at Central Valley, was thrown from his automobile and narrowly escaped death.

House Staff Resigns.—The house staff of the Washington Heights Hospital has resigned on account of Dr. Herman S. Jacobs, house surgeon, refusing to sign a paper certifying that a client of an insurance company had died. unless he, Dr. Jacobs, received the usual fee for his services. The superintendent insisted that the money go to the hospital fund, and Dr. Jacobs refused to sign the blank, and was reported to the chairman of the medical board, who suspended him. Believing Dr. Jacobs to be in the right, the staff, consisting of Dr. Aaron B. Cohen, senior ambulance surgeon, and Dr. David Linetsky, pathologist, decided to resign unless he was taken back. The resignations were accepted, and the staff left the hospital November 7.

OHIO

School in Tuberculosis Sanatorium.—The first school in a tuberculosis sanatorium is said to have been organized at the Franklin County Hospital, Columbus, to look after the mental welfare of ten patients of school age now under the care of the institution.

Staff Resigns.—The mmebers of the medical and surgical staff of the Mahoning Valley Hospital, Youngstown, with one exception, have sent in their resignations. The reason assigned for this is that "there seems to be lack of proper persons to take care of the sick. There are no facilities for taking care of accident or emergency cases."

State Should Supply Antitoxin.—The State Board of Health, at its meeting in Cincinnati, October 13, adopted a resolution that the state supply diphtheria antitoxin free, wherever it is needed. The board also requested the legislature to enact a law providing for the appointment of twelve medical inspectors of contagious diseases, and making medical examination compulsory in city schools, and optional in township and village schools.

Personal.—Dr. William A. Pitzele has been appointed a member of and elected president of the Board of Health of Lorain.——Dr. John S. Cherrington, Logan, has returned from Europe.——Dr. William H. Perry, Van Wert, sailed for Europe, November 17.——Dr. Edgar C. Davis, resident physician at St. Luke's Hospital, Cleveland, was operated on recently for appendicitis.——Dr. Clarence S. Ordway, Toledo, has given a contract for the immediate erection of an eighteen-room hospital on his property on the East Side.

A New Charity.—The Toledo Lying-in and Babies' Dispensary was opened October 26, under the direction of a board of governors, the medical members of which are Drs. Julius H. Jacobson and Park L. Myers. Dr. George B. Booth has been appointed superintendent of the dispensary and placed in charge of the maternity department, and Dr. Herbert E. Smead has been placed in charge of the babies' department. The dispensary is designed to provide nursing for patients in their own homes by visiting nurses, and to provide medical attention, medicine and food to infants and young children.

PENNSYLVANIA

Carnegie Gives Land.—Mr. Andrew Carnegie has given to the State of Pennsylvania 450 acres of land at Cresson for a tuberculosis sanitarium.

Favors Aid to Marine-Hospital Officers.—The Commercial Exchange, through its board of directors, adopted a resolution, November 11, requesting the Pennsylvania delegation in Congress to support proposed legislation in aid of the United States Public Health and Marine-Hospital Service. The measure is intended to provide more adequate remuneration for the officers of that service and for the payment of a salary to officers retired at the age limit or for physical disqualifications.

Philadelphia

Doctors' Charity Chooses Officers.—At the annual meeting of the Aid Association of the Philadelphia County Medical Society, held November 8, the following officers were elected: President, Dr. James B. Walker; vice-president, Dr. Jacob Shellenberger; secretary, Dr. Lewis H. Adler; treasurer, Dr. John B. Turner, and directors, Drs. Roland G. Curtin, Samuel W. Morton and Alexander R. Craig. The association was formed to give aid to the needy members of the county medical society and their families and other physicians in extraordinary cases. Its work is purely benevolent and the names of the beneficiaries are not known to the other physicians.

Personal.—Dr. S. Weir Mitchell has been elected president of the St. Andrew Society of Philadelphia.——Dr. I. Newton Snively, who underwent operation for abdominal abscess, November 9, is improving.——Dr. William T. Pride, Jr., has been appointed professor of pathology in the College of Physicians and Surgeons, Memphis, Tenn.——Dr. Albert G. B. Hinkle is recovering from a long and serious illness.——Dr. James K. Young was appointed associate professor of orthopedic surgery in the University of Pennsylvania faculty, November 9.——Dr. Walter L. Pyle gave a reception, November 13, to many of the physicians of the country, who had come to attend the dedication exercises of the new building of the College of Physicians and Surgeons.

Dedication of the New Hall of the College of Physicians of Philadelphia

The new home of the College of Physicians of Philadelphia was dedicated with fitting ceremonies, November 10 and 11. This society, organized January 2, 1787, is the oldest medical organization (not a state society) in the United States.

The society is a scientific and not a teaching body. Until recently the number of its fellows has been very small. It has never aimed to include the rank and file of the profession, but has had a selected fellowship, which even now numbers only 439 fellows, 40 associate fellows, of whom 11 are from Great Britain, and 4 corresponding members.

LARGE MEDICAL LIBRARY

The library of the college, with the exception of the Surgeon-General's Library at Washington, is stated to be the largest medical library in the world. It contains, excluding duplicates, almost one hundred thousand volumes. For the last few years it has increased at the rate of more than two thousand new volumes a year. The college contains some very rare material. It possesses one of the six copies of the first edition of Harvey's "De Motu Cordis et Sanguinis" to be found in the United States and has also the still rarer final leaf containing the errata. Among the many curiosities are a lock of Jenner's hair, Laennec's stethoscope, a set of Perkin's "tractors" and the knocker from the door of Ephraim McDowell. The college also contains the museum of the late Thomas D. Mutter, which was presented to the institution in 1856. This covers a floor space of 3,500 square feet and is provided with several galleries. This museum has an endowment of $30,000 to provide for its care and increase, and for the annual "Mutter Lecture."

THE NEW BUILDING

The new building, with furniture and fixtures, has been erected at a cost of $400,000, of which $100,000 was presented by Mr. Andrew Carnegie. The structure is a modern two-story fire-proof building of steel construction, with brick walls and limestone trimmings. It is 108 by 150 feet, situated on a lot 130 by 184 feet and is surrounded by three streets, thus assuring light and protection from fire on all four sides. The first floor contains the executive offices and is provided with two large lecture rooms with a capacity for one hundred persons, known as the Thomas Cadwalader Room and William Thompson Room.

The second floor contains a large auditorium capable of seating 500 persons. This room was furnished by the friends of Dr. S. Weir Mitchell and is known as Mitchell Hall. Several other memorial rooms are provided, and all, except one, have been named after deceased fellows. Special provision is made for fellows who are engaged in prolonged research work by a dozen small private rooms, in which they may study, and on leaving the room lock the door. This is a saving of time and trouble both to the student and library officials, and has the advantage of freedom from all interruption.

LIBRARY AND READING ROOM

The windows of the library are provided with wire glass in metal frames and there is further protection from fire by rolling steel fire shutters, which drop automatically at a certain temperature. The library is also cut off from the rest of the building by fire doors. Space in the library has been provided for 300,000 volumes and ample provision has been made for large future extension whenever necessary. A large reading room is provided, which will accommodate fifty readers, and the journal room, opposite, contains accommodation for fifty additional readers. There are 850 medical journals on file in this room. Six shelves without partitions run around the entire room, three of which are horizontal. Above each horizontal shelf there is another shelf inclined about forty-five degrees. On the inclined shelf the latest number of each journal is placed, while immediately below it, on the horizontal shelf, are all loose preceding numbers of the same journal, awaiting binding as soon as the volume is completed. The library is open to all the non-medical public as well as to the entire medical public of whatever school.

ACADEMICAL PROCESSION

The fellows and guests assembled and proceeded to the entrance to the new building, where the presentation was made by Dr. William J. Taylor, secretary of the building committee. The hall was accepted on behalf of the president and officers and in the name of the fellows of the College of Physicians of Philadelphia by the vice-president, Dr. George E. de Schweinitz.

THE GUESTS

Dr. James Tyson, president, introduced the visiting guests, who spoke, in part, as follows:

JOHN SHAW BILLINGS, M.D., representing the New York Public Library:—"I offer [illegible] only of the New York Public Library, but [illegible] public libraries, on your success in obtaining and properly housing this collection of books which is perhaps the most complete in the world. It has an added value in that it contains the books of Dr. John Stockton Hough. I speak also as a delegate of the Carnegie Institute of Washington and present congratulations from that body."

CHARLES LOOMIS DANA, M.D., representing the Academy of Medicine of New York:—"In bringing the message of fraternal greetings and congratulations on your present great feat, I speak not alone as a representative of a kindred institution, but with a note of real personal feeling, for I have experienced the hospitality of this college and know its worth and work. The New York Academy of Medicine is the junior of this college by sixty years. It owes its existence to the widows and orphans of medical men and shows how the poor and humble may be an inspiration to mighty things. Through it New York first organized a board of health and the academy has since its beginning aided nearly every measure for public health and medical science. In six decades our membership has grown from 184 to over a thousand and a waiting list exists."

REGINALD HEBER FITZ, M.D., spoke for the Boston Medical Library:—"The College of Physicians of Philadelphia and the Boston Medical Library meet on common ground in their effort to take their place among those seeking nothing for themselves but all for the race."

WILLIAM SYDNEY THAYER, M.D., representing the Medico-Chirurgical Faculty of Maryland:—"I present congratulations, not perhaps of a sister society, but of a child, for a large number of our founders gained inspiration from members of this venerable institution, and we in Maryland have ever sought refreshment from the quickening current which has flowed from the lips of your students, philosophers and poets. May this institution ever serve to broaden the horizon of the physician, to stimulate justice, liberality, tolerance, and bring him nearer to his fellow man, giving to the world the highest usefulness, counsel, and advice."

FREDERICK P. HENRY, M.D., honorary librarian, Library of the College of Physicians of Philadelphia:—"Our library is in the front rank of the medical libraries of the world and second to none as a working library. I would call particular attention to the numerous small rooms for special research in which the student may have absolute privacy. The books are a collection of animate objects which have not only stimulated but compelled progress. They forced us out of our home in the Mercantile Library in 1854 and again they forced us out of the old picture house in the Pennsylvania Hospital grounds in 1863, and finally they drove us, with metaphorical whips and scourges, out of our last home and forced us like a swarm of bees into this hive of learning. Like a swarm of bees also there was needed a metallic sound to make us settle and gold has been literally poured out at our feet. The bookstacks have space for 300,000 books with ample room for extension, so that the youngest member need not anticipate the expense of another removal during his life time. I cannot offer you what you already possess, the freedom of this great library, but I can congratulate you and ourselves on the fact that it is contained in the finest building of its kind in either hemisphere and that the jewel is worthy of its casket."

CONFERRING OF ASSOCIATE FELLOWSHIPS

ARCHIBALD BYRON MACALLUM, M.A., M.B., Ph.D., Sc.D., LL.D., F.R.S., was presented by Albert Philson Brubaker, M.D., who said in part that for his services to the cause of higher education and for the supreme worth of his personal character Dr. Macallum had been honored in large measure by universities and scientific associations at home and abroad, for which reasons the fellows of the College of Physicians desired to express their appreciation by conferring on Professor Macallum the title of associate fellow.

To the presentation Dr. Tyson responded and in like manner to the subsequent presentations: "Selected from among those eminent scientists of the country by unanimous vote of the council, confirmed by a like vote of the college, you have been made an associate fellow of the College of Physicians of Philadelphia, in evidence of which I present to you the certificate of the college, signed by the president, vice president, the secretary and treasurer and the censors of the college."

OLIVER FAIRFIELD WADSWORTH, M.D., was presented by George E. de Schweinitz, M.D., as "A pioneer in the early medical work of the country; a teacher who has sent forth students fully equipped; a clinician distinguished for accuracy and keenness of observation, an ophthalmologist, physician and surgeon who has upheld the standard of the profession."

EDWARD GAMALIEL JANEWAY, M.D., LL.D., was presented by James C. Wilson, M.D., as a "master clinician, distinguished writer, comprehensive teacher, wise consultant, and courteous gentleman."

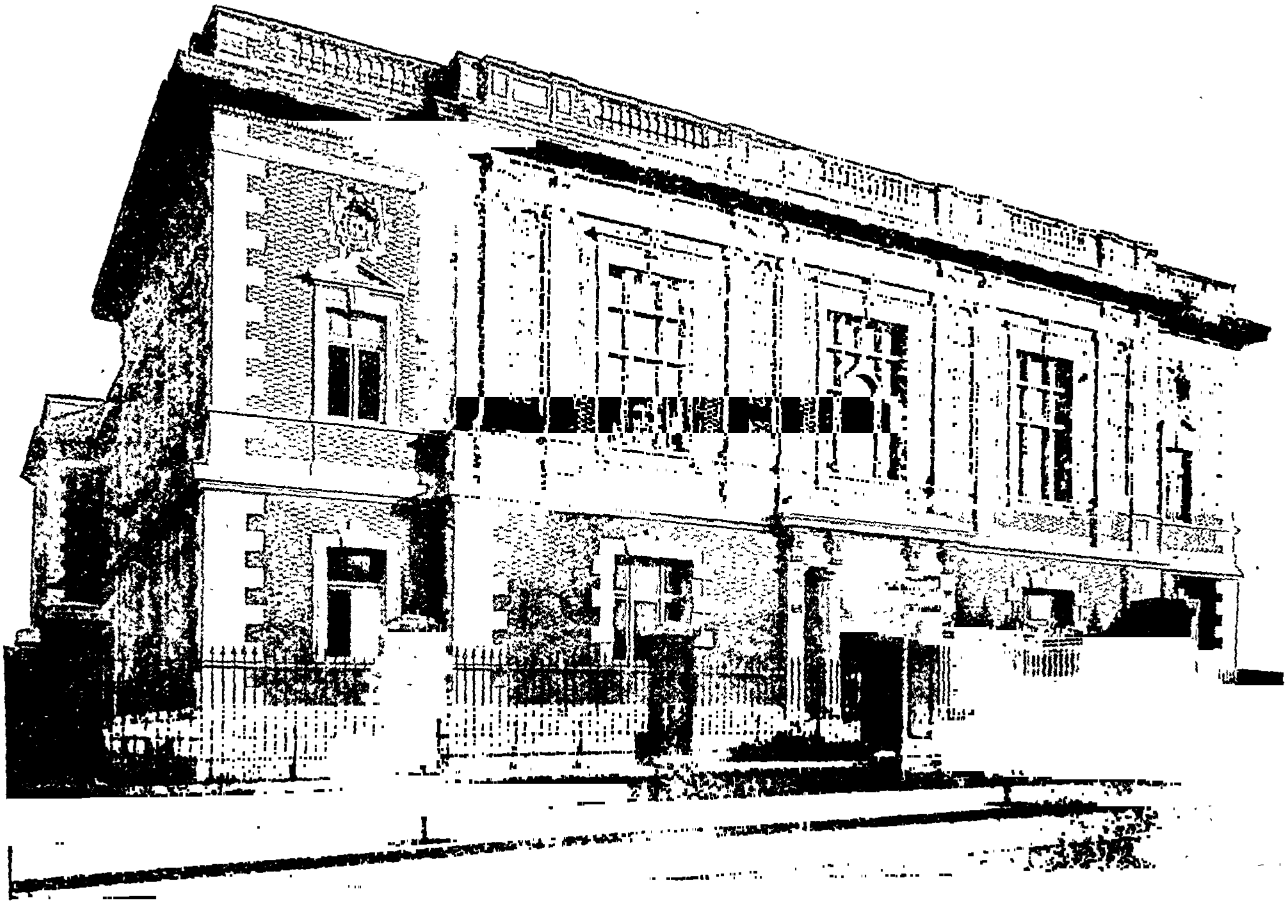
CHARLES LOOMIS DANA, M.D., was presented by Charles K. Mills, M.D.:—"When the College of Physicians of Philadelphia selects for a special honor we are assured that the choice is determined by exceptional merit. Such merit is possessed by the candidate whom I have the honor to present. Born among the rugged hills of New England, he has by a life of ever-increasing distinction made faithful return for his inheritance of capacity. His success in neurology, his chosen department of medicine, was assured from the outset. He is the author of one of the best text-books on neurology and psychiatry ever issued from an American press."

FRANK BILLINGS, M.D., was presented by John H. Musser, M.D., who said in part:—"Beloved physician of patriotic vision, skilful in interpretation, masterful in treatment, scientist, wise and earnest seeker of truth, you have emblazoned the path of many young men who, inspired by your conceptions, have been earnest workers in medical science. As president of the State Board of Charities of Illinois you have shattered the political bonds of the various institutions under your care and have brought to the inmates of the institutions careful management and scientific treatment. Recognizing the commanding features of your career the fellows of the College of Physicians have by one voice asked that you be presented to the president and receive the certificate of associate fellowship, knowing full well that you will honor it far more than it can ever honor you."

GEORGE WASHINGTON CRILE, M.D., was presented by Dr. William L. Rodman:—"The candidate whom I present has placed new paths in surgery and has compelled a gratified profession to acknowledge him as a leader. Perhaps his most noteworthy publication was on hemorrhage and transfusion. Busy as he must have been in the preparation of such a monograph he has found time to devise new surgical operative instruments and to contribute largely to current medical literature."

FRANKLIN PAINE MALL, M.D., was presented by George A. Piersol, M.D.:—"In bringing about the larger recognition of anatomy in surgery Dr. Mall has rendered conspicuous service. During his career as educator he has striven to arouse a love for research, and largely through his efforts this country now possesses two journals of acknowledged merit devoted exclusively to anatomy."

Cablegram congratulations were received from the Royal College of Surgeons of Edinburgh, the College of Surgeons of England, and from William Osler. A set of resolutions came from the Boston Medical Library and letters from two fellows, Drs. J. Cheston Morris and Horatio C. Wood, and from the representative of the library of the Surgeon-General's office, U. S. Army, Dr. Robert Fletcher, who were unable to be present.



THE NEW BUILDING OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA

DEDICATORY ADDRESS

The president, JAMES TYSON, M.D., delivered the dedicatory address:—"Of the three occupations of men which are dignified by the title of profession—namely, the ministry, the law, and medicine, that of medicine has been especially characterized by a desire on the part of its members to unite for mutual improvement. The first effort toward organized medical societies in the English colonies of North America appears to have been in Boston in 1735. The College of Physicians was organized in 1787 and while the third of the medical societies organized in Philadelphia was the tenth of American societies, so far as can be learned it is the oldest in existence of American societies which is not a state organization. As early as 1767 Dr. John Morgan began to agitate the subject of a College of Physicians, but was rather severely sat on by one of the proprietors, Thomas Penn. As a result the charter was refused and the project abandoned for the time being. On Jan. 2, 1787, however, the first meeting after its full organization was held. Dr. John Redman was the first president and held office for eighteen years. The vice-president was Dr. John Jones, great grandson of Dr. Thomas Wynne, who came over with Penn in the ship *Welcome*. The constitution provided that the officers should be chosen annually, and this practice continues to the present day. The first paper read before the college was by Dr. Rush at the second meeting, Feb. 8, 1787, on 'The Means of Promoting Medical Knowledge.' The college early assumed a guardianship over the health, safety, and even morals of the community.

"The circumstance which made the first decade in the life of the college the most stirring and interesting in its history was the presence of yellow fever. On Aug. 25, 1793, a special meeting was held 'to consider what steps the college should take consistently with duty to their fellow citizens in connection with the prevalence of a fever of very alarming nature in some parts of the city.' Directions for preventing the further progress of the fever with comments on the inefficiency if not the danger of fires kindled as a means of checking the progress of the fever and placing more dependence on the burning of gunpowder were promptly sent to the citizens.

"It was further stated that 'the benefits of vinegar and camphire are confined chiefly to infected rooms, and they cannot be used too frequently on handkerchiefs or in smelling bottles by persons whose duty calls on them to visit or attend the sick.' On Nov. 26, 1793, in answer to the inquiry from Governor Mifflin to President Redman whether or not yellow fever was an imported disease a reply was adopted to the effect that the fever was imported in vessels about the middle of July. Cleanliness of the streets, the use of gunpowder as a disinfectant, and of slacked lime in privy wells was recommended. In 1798 when the fever again broke out as a result of a special meeting of the college a committee was appointed to wait on the Board of Health to recommend the removal of all families between Walnut and Spruce Streets and the east side of Front and the river; also to remove the shipping between Walnut and Spruce Streets to a proper distance. The fever prevailed with intermissions and remissions from 1793 to 1798. Two founders of the college died of it and many more physicians were very ill. At one time only three were able to do duty outside their own houses.

"In 1798 was organized the American Academy of Medicine of Philadelphia. It is said to have been organized with a view to the study of yellow fever, but it was also in evident opposition to the College of Physicians.

"The college in its infancy and for some time afterward was very poor. In February, 1883, Dr. S. Weir Mitchell presented $5,000, subsequently increased to $7,000, to establish an entertainment fund. This generous gift and its purpose was followed by the appointment of an entertainment committee which has been called upon to exercise its function on several occasions. The most important event in the history of the college after its organization was the Centennial Anniversary, celebrated Jan. 3 and 4, 1887. On January 2 the actual anniversary, the day was bitterly cold and is especially associated in my mind with the presence of Dr. R Palmer Howard, then professor of medicine in McGill College, Montreal, who was my guest and whom I took in the afternoon to old St. Peter's church on Pine Street, where lies buried John Morgan, one of the most brilliant and accomplished founders of the college.

"The occasion of the centennial also marked the completion of the then new college hall at Thirteenth and Locust Streets by the addition of the third story at a total cost of $67,256.50, including the site, which cost $14,408. Yet the total investment is insignificant as compared with what has been expended for this, our latest home, appointed as no building for a like purpose ever was. One of the most important functions of the college is the stand it has taken against encroachment on the right to use, humanely, animals for investigating the action of medicines and determining the causes, prevention, and cure of disease. The subject of quarantine has at all times received interested attention. The college has always been ready to render, to the extent of its ability, aid to members of the profession who have suffered in public calamity. In February, 1891, a committee was appointed to represent the college before the legislature in advocacy of a bill to establish a state board of medical examiners and licensers, and in opposing a bill providing a state board of medical education. The bill establishing the State Board of Medical Examiners was passed and has been of great service in advancing the standard of medical education.

"Of the library I may state that the total number of bound volumes up to Nov. 1, 1909, is 81,018; general library, 63,890; Lewis library, 13,536; S. D. Gross library, 3,375; Obstetrical Society library, 217. There are also unbound reprints and transactions, 8,202; unbound theses and dissertations, 23,711, and unbound pamphlets, 70,213. Between 2,000 and 3,000 volumes are purchased annually and many are donated by authors, publishers and friends."

THE BANQUET AND THE RECEPTION

On the evening of the dedicatory exercises a banquet was held in the Bellevue-Stratford Hotel. Nearly 500 persons were present. Dr. George E. deSchweinitz was toastmaster and the following toasts were responded to: "The Old College and the New," Dr. S. Weir Mitchell; "Libraries and Their Foundations," Mr. Andrew Carnegie; "The College Library and Its Treasures," Dr. William W. Keen; "The College and Its Civic Relations," Hon. Hampton L. Carson; "The College and Its Traditions," Dr. Arthur V. Meigs.

On November 11 the new building was thrown open to the inspection of the public and in the evening a reception was attended by over 500 persons. Preceding the reception the guests and visitors gathered in the assembly hall and were addressed by Dr. S. Weir Mitchell. Dr. James Tyson, president of the college, presided.

GENERAL NEWS AND COMMENT

Individual Drinking Cups.—The Norfolk and Western Railway has installed in each of its coaches slot devices from which individual drinking cups may be secured by passengers.

Prize for Aid for Deafness.—Professor Cozzolino of Naples, Italy, was the official delegate from Italy to the International Congress for Otology at Budapest, and he has since founded a $200 prize to be awarded at the next international congress, to be held at Boston in 1912, for the best work on the treatment of progressive deafness or a mechanical device for relieving it.

Personal.—By order of the Secretary of the Navy, November 11, the controversy as to whether line officers or medical officers shall command a hospital ship was decided when Surgeon George Pickrell, U. S. Navy, was detailed to command the hospital ship, *Solace.*——Dr. Varone Suarez, Havana, has been appointed secretary of sanitation of Havana, Cuba, vice Dr. Mathias Duque, resigned.

Prize for Work on Typhus Fever.—The Mexican government has authorized the National Medical Academy to announce a typhus prize fund of $25,000 (50,000 pesos): $10,000 will be awarded to the discoverer of the cause of exanthematous typhus, and $10,000 for the discovery of its mode of transmission or a curative serum, and $5,000 to the investigator whose work is judged most useful in helping toward such a discovery. The competition is international but all articles must be in Spanish and be in the hands of the secretary of the Academia N. de Medicina, Mexico, before Feb. 28, 1911.

Hookworm Commission.—Mr. John D. Rockefeller, who has given $1,000,000 to investigate and combat the hookworm disease, has selected the following commission to have charge of the administration of the fund: Drs. William H. Welch, Baltimore, Simon Flexner, New York City, and Charles Wardell Stiles, U. S. P. H. and M.-H. Service; President Edwin A. Alderman of the University of Virginia; Chancellor David F. Houston of Washington University, St. Louis; P. P. Claxton, professor of education in the University of Tennessee; J. Y. Joiner, state superintendent of education of North Carolina; Walter H. Page, editor of the *World's Work*; Principal H. B. Frissell of Hampton (Va.) Institute, Frederick T. Gates, Starr J. Murphy, and John D. Rockefeller, Jr.

Lombroso's Brain.—According to the wishes of the late Professor Lombroso, his autopsy was held in the amphitheater of the medical school at Turin. A number of professors and students were present. Evidences of interstitial myocarditis and atheromasia of the coronary arteries were found but the arteries in the brain were in good condition. Also in compliance with the wishes of the deceased, the brain was removed from the skull and given to Professor Boero to be preserved in the Institute of Normal Anatomy. It weighed 1,308 grams. Lombroso had written a romance and poems by the age of 10, the next year two tragedies modeled on Alfieri's, and had published two monographs on Roman archeology before he was 12. A year or two later he took up sociologic studies based on linguistic analysis of the Greek, Hebrew, Sanskrit, Coptic and Chinese, and before he entered the university had written two works on natural science.

New Medical Association.—The American Association for the Study and Prevention of Infant Mortality was organized at New Haven, November 13, as the result of the convention of the American Academy of Medicine for the discussion of that topic. The following officers were elected: President, Dr. J. H. Mason Knox, Jr., Baltimore; vice-presidents, Prof. C. E. A. Winslow, biologist-in-chief of the laboratory of sanitary research, Massachusetts Institute of Technology, Boston, and Homer Folks, secretary of the New York State Charities Aid Association, and secretary, Dr. Henry I. Bowditch, Boston.

CANADA

Civic Medical Officer.—The active attention of the executive committee of the New Brunswick Medical Association is at present engaged on the question of the appointment of a civic medical officer or civic health officer, whose duties are to include the examination of public school children and the care of the health of the children. At the last meeting of the executive committee a resolution to this effect was adopted.

Offenders Sentenced.—Mrs. Susan Labertis, a colored woman of Woodstock, charged with breach of the medical act, in that she practiced medicine without a license, was found guilty in the Toronto police court, September 7, and fined $50 and costs. ——Charles Williams, christian scientist of Virden, Man., is said to have been sentenced to serve two years in prison for failing to call in medical aid while treating for pneumonia a child who subsequently died.

Medical College Opens.—The opening lecture of the annual session of the medical faculty of McGill University was given by Professor Wolbach, October 1. Principal Peterson, who presided, reported the generous gift of Lord Strathcona, which has made possible the new medical building of the University. It was announced that arrangements have been made with the authorities of Montreal General Hospital to maintain an additional clinic for the benefit of English-speaking students.

Personal.—Dr. Frederick J. T. Old, Port Colburne, has been elected president, and Dr. Ernest L. Garner, Welland, secretary-treasurer of the Welland County Medical Association. ——Dr. John J. McFadden, Neepawa, Man., has been elected medical superintendent of the Brandon Hospital for the Insane, vice Dr. James J. Anderson.——Dr. George Bayham, Winnipeg, has returned after ten months abroad.——Dr. and Mrs. Henry Meek, London, have returned from Europe.—— The Manitoba Medical College has appointed Dr. E. J. Evatt to take charge of the department of anatomy.——A complimentary dinner in honor of Dr. Leonard G. Rowntree, Baltimore, was given at the Tecumseh House, London, by the Faculty of the Medical School and the executive of the alumni association.——Dr. Archibald R. B. Williamson has been appointed medical health officer of Kingston, Ont., vice Dr. John H. Bell.——Dr. John W. Wigham, Toronto, has been appointed associate coroner for that city, and Dr. Hugh C. McLean, Guelph, associate coroner for Wellington county.

Annual Meeting of Medical Council.—On October 13 and 14, the annual meeting of the Council of the College of Physicians and Surgeons of Manitoba was held, and the following officers elected: President, Dr. Thomas M. Milroy, Winnipeg; vice-presidents, Dr. John J. McFadden, Neepawa; registrar, Dr. John S. Gray, Winnipeg (reelected); treasurer, Dr. James Patterson, Winnipeg (reelected); representatives on the council of the University of Manitoba, Drs. Charles W. Clark, Thomas M. Milroy, Arthur W. Moody, and James N. Hutchison, and representative of the college on the Board of Studies of the University, Dr. Thomas M. Milroy. At a meeting of the council, held later, it was decided to raise the registration fee from $75 to $125, to take effect Jan. 1, 1910, and to abolish the annual fee of $2.——The Manitoba College of Physicians and Surgeons has offered to hand over to the University of Manitoba, without reservation, the new medical college, site and equipment, valued at $100,000, provided the university is freed from denominational control and is absolutely placed under the control of the state.

LONDON LETTER

(From Our Regular Correspondent)

London, Nov. 5, 1909.

Outbreak of Scarlet Fever and Diphtheria

London is at present suffering from a serious outbreak of scarlet fever and diphtheria, the number of cases considerably exceeding the usual autumnal rise in these diseases. Patients are being removed from their homes to the fever hospitals at the rate of 600 a week and the number of cases admitted amount to 3,805.

Hindus Demand that Appointments Be Thrown Open to Them

The civil medical administration of the teeming millions of our vast dependency of India is controlled by the officers of the Indian medical service, who are all Europeans. The government has established a number of medical colleges for the training of natives in western medicine under professors appointed from the Indian medical service. When these natives become qualified they form what is called the subordinate medical service. They are eligible for civil and military practice but not for the higher appointments. In the Indian army (which consists of natives officered by Europeans) they can attain no higher rank than that of captain. As the number of European physicians in India is small compared to the population the native physicians are now numerous and they fill a large number of government appointments in the hospitals, on plague duty, in the jails and in the sanitary administration generally. They form the great majority of the private practitioners; excepting the medical missionaries, there are scarcely any European physicians outside the army in the country. As stated in a previous letter to The Journal, Lord Morley, the secretary for India, has come to the conclusion that the demands on the medical service of the Indian army by civil practice are too great, that they must be restricted in the future and that civil appointments shall be made so far as possible in the future of private practitioners. The members of "the independent medical profession," i. e., the native physicians, have taken the opportunity of pressing their claims. They have held a meeting at Bombay and unanimously adopted a memorial asking that all civil medical appointments under the government shall be thrown open to natives and the present monopoly of the higher posts by the Indian medical service be abolished. They recommend that the Indian medical service shall be purely military. They also desire that multiple professorships at the medical colleges shall be abolished and that professors should not be allowed also to hold appointments on the staffs of hospitals. They anticipate that if their recommendations are adopted a saving of $1,000,000 annually to the state will result. As there are now many highly competent and well trained native physicians in India it does not seem that the reasonable request that they shall be allowed to compete for medical appointments in their own country can be refused.

A Physician's Heroism

In the early morning an explosion occurred in the Darran colliery, South Wales, before the workers on the night shift had left. The ordinary approach to the mine was completely blocked and the only way of access was by the shaft of another pit four miles away. A relief party, accompanied by Dr. Turner, the colliery surgeon, descended the pit and endeavored to reach the other pit. One after another they were overcome by the choke-damp and five died. The physician had a narrow escape. He repeatedly risked his life in heading the relief party and at last collapsed. His companions endeavored to rescue him but were so overcome by the choke-damp that they had to abandon him. After a time they were able to return and found him lying in the roadway still alive. He was carried to a place of safety and oxygen was administered. He was then taken in a comatose state to the Cardiff Infirmary. Twenty-nine lives were lost from the explosion.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Oct. 28, 1909.

The Affair of the Ophthalmologic Clinic

The difficulties in finding a first-class ophthalmic surgeon willing to accept the appointment as successor to Schnabel are ever increasing. At first there was an apparent tendency on the part of the government to neglect the recommendation of Professor Hess of Würzburg by the medical faculty, then Hess refused to accept the office, without very substantial changes and adaptations, which required money. The government not complying with his wishes he declined the honor. Then Professor Dimmer of Graz, recommended in the second place, was offered the clinic. He made conditions nearly identical with those of Hess: enlargement of the clinic, reform of the present insufficient laboratories and teaching accommodations, and modern outfit. This was refused, whereupon he too declined. The splendid new general hospital, parts of which have been opened already, provides a real palace for an ophthalmic clinic, but this will not be erected before 1914. Thus, five years would have to be spent in the old building. Anyone who knows the present building will easily understand the attitude of the two surgeons. The students are now in danger of not enjoying the teaching of a first-class ordinary professor, although the surgeon in charge of the clinic at present is also a very good man. On the other hand, the standing of the Vienna medical school must be seriously hampered by such conditions.

Honors to a Dead and to a Living Teacher

In memory of the late Professor Albert, a surgeon whose name is well known beyond the frontiers of Austria, a relief tablet was unveiled in the hall of the university a short time ago. The tablet shows the surgeon at the side of a young woman anesthetized, explaining to his students the operation he is performing. It is a fine piece of art; the likeness is very striking to all those who had the privilege of knowing the surgeon. Albert was professor of surgery in Vienna from 1881 till 1900; he was a keen observer, a strict logical thinker, and one of the most successful teachers known in medicine. His methods of teaching were actually the sole reason that the Vienna school retained for many years the standing gained for it by Billroth. At the foot of the tablet a wreath has been placed by the surgical clinic, bearing the inscription: "Magno medico, maximo magistro, grata animo."

A few days later, a living physician, Professor Leopold Oser, celebrated his seventieth birthday among a number of his devoted friends and scholars. He is one of the pioneers in the study of the the gastro-intestinal tract; the chief methods of investigation of the pathology of the stomach are due to his clear mind. He was also one of the initiators of the Vienna Poliklinik, which has developed since to such importance as an annex to the general hospital as regards teaching. A very valuable contribution by Professor Oser to the pathology of cholera was and is still regarded as one of the best treatises on this subject. Among the numerous honors received by Oser was also a splendid address from the Vienna Medical Society (*Gesellschaft der Aerzte*), of which he was one of the presidents.

The Institute for Teaching of Physics

A similar incident is now attracting attention toward the unsatisfactory conditions in certain branches of our university institutes. Every medical student here must study physical science for at least one year at the physical institute. This is over sixty years old and was inadequate twenty-five years ago. It is an old, unhealthy, cold building with poor acoustic properties, capable of holding, in the laboratories and lecture hall, altogether about 100 students. Four hundred students have taken up these studies just now, and when the new professor, Dr. Lecher, a renowned investigator and teacher, began his lectures a few days ago, the impossibility of admitting all or even half the students caused an outburst of indignation from them. To force the government to a radical reform a strike was organized; the professor, who naturally sympathizes with his students, was asked to stop all his classes until all those who had a right to hear his lectures were able to do so. So the shameful condition now exists that students are debarred from learning because some very economical official does not care to have the ordinary slow course of red-tapeism disturbed. The daily press has aroused public opinion and now things will become very lively unless a definite step forward is soon made.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Oct. 27, 1909.

The City Government and the Medical Profession

The mayor (*Magistrat*) of Berlin has again given the medical profession occasion for serious complaint. As I have previously told you examination bureaus were established about a year ago by the state and by the city (and suburbs) in which hygienic examinations were made free of charge. While all the other stations undertake examination of tuberculous material without fee, the city government of Berlin has refused to permit such examination by the municipal laboratory. The alleged reason for this determination is that there is no call for such examinations by the city laboratory since the well-to-do people can get the work done by their private physicians or in private laboratories and the tuberculosis dispensaries are ready to perform similar service for the patients of the krankenkassen and the poor. The city council did not concur in this decree of the administration, and requested the mayor to permit free examination of tuberculous material, but no change was made. A few days ago Privy Councillor Proskauer, of the Institute of Infectious Diseases, on account of unpleasant experiences, sent a new request to the mayor for permission to make free examinations for tuberculous patients. His request was refused and a new regulation announced which provides that half the fee of six cents (0.25 marks) must be advanced by every physician who sends a specimen of sputum for examination. The examination is made dependent on the payment of this sum. If this advance payment is not made within three days, the material for examination shall be destroyed. This senseless order, so contrary to the purpose of an examining laboratory, will be understood if one reflects that the president of the board in charge of this branch of the city government is a physician 71 years of age, who for a long time has been unfit to supervise the important work of his office, to say nothing of carrying it on. Although the medical profession in society meetings and in the press has repeatedly proposed that the organization of the personnel of the municipal health office be improved and especially that this unfit representative of the municipal administration should retire, the municipal authorities have so far continued the inadequate arrangements. It is to be hoped that the storm of protest which has been raised among physicians and in the press by this latest order will have the effect of securing finally an organization of sanitary matters suitable to the capital of the German empire.

Care of Patients With Advanced Pulmonary and Laryngeal Tuberculosis.

The imperial chancellor in a circular letter directed to the various federal governments recommended for consideration certain principles which have been laid down by the imperial health office regarding the establishment of institutions for the care of sufferers from advanced pulmonary and laryngeal tuberculosis. These propositions are as follows:

In addition to the regulations which have the purpose of making the germs from tuberculous patients harmless the attempt should be made to isolate patients with open pulmonary or laryngeal tuberculosis unless they are already in sanatoria. For this purpose it is recommended:

1. As many of this class as possible should be retained for the longest possible time in the general hospitals. In these institutions the consumptives should be separated from other patients in special rooms or, if it is feasible, in wards in separate buildings which should be constructed on the plans approved for sanatoria, with open porches, etc. Provision for such arrangements should be made in all general hospitals in process of construction.

2. Where a need exists, as in large cities on account of the overcrowding of the general hospitals, tuberculosis hospitals should be erected in the neighborhood of the city in some healthful, wooded locality.

3. In the tuberculosis hospitals or in the tuberculosis departments of the general hospitals the cure of the patients should be made a prominent aim in addition to the isolation. The construction of institutions which shall serve for the reception of unimprovable tuberculous invalids in the last stages (*Pflegeheime, Invalidenasyle*) is not at present recommended.

4. Measures should be provided by which indigent families of consumptives who have been received into the hospitals for the longest possible stay shall be assisted in a financial way during this period. Those numerous consumptives who, partly on account of still persisting ability to work and partly from other reasons, will not enter the hospitals should be placed under conditions that will, as far as possible, limit the liability of infection of their environment. This task devolves on the institutions charged with the care of such patients, more particularly the tuberculosis dispensaries (*Fürsorgestellen*) which, in addition to the utmost practicable isolation of patients in their homes, should take care for the betterment of dwellings and the education of the patients and their environment in hygienic principles. In the fulfilment of this task they need the abundant support of the municipal authorities and communities.

5. Provision should be made for a sufficient number of laboratories in which gratuitous examination of sputum shall be made.

6. The managing boards of all institutions serving for the reception of consumptives, including popular sanatoria and tuberculosis dispensaries should be constantly in touch with each other in order to establish uniform rules by which the entrance and discharge of patients from time to time shall be governed.

Cholera in Prussia

In the last few days a few cases of cholera have been discovered in East Prussia, all of which, however, are to be attributed to introduction from Russia and therefore give no occasion for alarm.

Contemplated Increase in the Price of Medicines

The demand of the pharmacists for an increase in their charges for medicines on account of the general increase in the cost of living is likely to be granted by the ministry. In this way, however, the increase of expense indeed never comes to an end for the increase of one item involves an increase in others. If the price of medicines and medical services is raised, the butcher and the grocer naturally demand more for their wares and if the butchers receive more money, the doctors and the pharmacists will naturally charge more for their services. It is thus a vicious circle.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Oct. 29, 1909.

Lectures on Educational Hygiene

The French League for Educational Hygiene (*Ligue française pour l'hygiène scolaire*), the purpose and workings of which I have already described (The Journal, Sept. 29, 1908, li, 1094), has organized under the auspices of the School of Higher Social Studies (*Ecole des hautes études sociales*), during the winter semester of 1909-1910, a series of lectures on educational hygiene. The lectures and subjects are as follows: Professor Calmette, director of the Pasteur Institute of Lille, "Hygiene in Education"; Dr. Gallois, "Organized Cooperation of Parents and Teachers to Improve the Physical, Intellectual and Moral Hygiene of the Schools"; Dr. de Pradel, "Cooperation Between Physicians and Teachers"; Dr. Pierre Regnier, "Reduction of the Number of Hours for Study in Order to Give Time for Physical Education"; Dr. Cayla, "Educational Walks and Tours." Besides these lectures given by physicians, a certain number will be given by the members of the teaching profession on the subject of open-air schools, rural and family boarding-schools, vacation colonies, open-air games in city schools and the teaching of manual crafts in the schools. Teachers and physicians will be invited to take part in discussions following the lectures.

Opening of the American Hospital in Paris

On October 28 took place the official opening of the American hospital at Neuilly-sur-Seine (one of the suburbs of Paris), Boulevard du Château 55, in the presence of M. Doumergue, Minister of Public Instruction, Messrs. Henry White, United States ambassador, John J. Hoff, vice-president of the council of administration, the members of the board of directors and the medical staff. The hospital contains twenty-five beds in separate rooms, with bathrooms, the equipment being according to the latest hygienic requirements. The hospital, which was founded by certain Americans residing in Paris, will receive in the first place sick and needy Americans, who will be cared for free. Well-to-do Americans may likewise be cared for; from these the hospital will exact no fixed charges, but will receive donations toward the general fund. Two beds will be reserved for emergency cases without regard to the nationality of the patient.

Monument to Professor Liégeois

The monument, raised by international subscription, to Prof. Jules Liégeois, one of the founders of the famous Nancy school, whose tragic death was mentioned in The Journal, Sept. 12, 1908, li, 929, was unveiled October 24 at Damvillers, department of the Meuse, Liégeois' native city. The monument consists of a bust of the professor and is on a granite pedestal in the center of the public square of the city hall of Damvillers. Besides an official delegation from the University of Nancy, other French and foreign scientists were present at this tribute to the memory of the first jurisconsult who studied the relation of hypnotism and suggestion to criminal law and legal medicine.

Cholera in Belgium

According to official information, there had been, on October 28, six deaths due to cholera at Boom, Belgium. This is the first time that cholera has been officially acknowledged in Belgium since 1892. The foreign governments were informed.

Pharmacology

MEAT AND BEEF JUICES

Report of the Council on Pharmacy and Chemistry

The following was submitted to the Council by a subcommittee:

> *To the Council:* While meat extracts contain only traces of coagulable proteids and have little food value, meat juices are prepared by a process which ensures the presence in the finished product of considerable quantities of coagulable proteids and they therefore have considerable value as foods. Many preparations which are sold as beef juices or meat juices have no right to these designations. Since the public and physicians are likely to be misled by the names given to these products and by the false claims which are made for them as foods and depend on them in the nourishment of the sick, it is important that their composition and their value as foods should be known.
>
> In the following report is presented the results of an examination of some of the commercial products found on the American market. The report shows that *Wyeth's Beef Juice* (John Wyeth & Bro., Philadelphia), *Bovinine* (The Bovinine Co., New York), *Carnine* (Carnine Co., Fougera & Co., New York), and *Valentine's Meat Juice* (M. J. Valentine, Richmond, Va.) are sold under names which are incorrect, that their composition is not correctly stated by the manufacturers and that false and misleading statements are made in regard to their value as food.
>
> It is recommended that the products named be refused recognition for conflict with rules 1, 6 and 8. Since these preparations are typical of many others on the market, and as their use is a menace to the public health it is recommended that the report be published.

This report was adopted by the Council.

W. A. Puckner, Secretary.

Beef or meat juices are clearly to be distinguished from beef or meat extracts. The word "juice" applies solely to the fluid portion remaining in fresh meat after proper cooling and storing and may be obtained by pressure or diffusion with or without a low degree of heat. Under heavy pressure freshly chopped meat will yield from 25 per cent. to 40 per cent. of a thick reddish juice and if the meat is previously frozen or heated to 60° C., as much as 50 per cent. may be obtained. This gives some idea as to the probable cost of preparing beef juice at home. The chief characteristics of meat juice are the presence of a considerable proportion of coagulable protein and a low content of meat bases. The above represents the nature of these commodities as usually understood by the medical profession as is clearly shown by this quotation:[1]

> "One or two teaspoonfuls of this (meat juice) are added to a teacupful of cold or warm water, which, however, must not be boiling, or otherwise the albumin would be coagulated, but it may, however, be sufficiently warm to drink comfortably."

Beef juice is considered by some physicians of much dietetic service and believed to represent liquid food in concentrated form. W. O. Atwater,[2] relative to this product, says:

> "Beef juice obtained from the best steak which has been merely warmed through over the coals and then entirely deprived of soluble substance by a screw press, is undoubtedly the most concentrated of the liquid foods."

The latter authority gives a number of analyses of beef juices prepared under known conditions.

DEFINITION OF MEAT JUICE

Meat juice is defined by the standards committee of the Association of Official Agricultural Chemists as the fluid portion of muscle fiber obtained by pressure or otherwise, and may be concentrated by evaporation at a temperature below the coagulating point of the soluble protein. The solids contain not more than 15 per cent. of ash, not more than 25 per cent. of sodium chlorid (calculated from the total chlorin present), not more than 4 nor less than 2 per cent. of phosphoric acid (P_2O_5), and not less than 12 per cent. of nitrogen. The nitrogenous bodies contain not less than 35 per cent. of coagulable proteins and not more than 40 per cent. of meat bases.

Meat juices of commerce are supposed to be made by subjecting properly prepared meat to heavy pressure with subsequent concentration of the juice *in vacuo* at a low temperature. The latter is necessary because if the temperature is raised to any material extent the valuable coagulable, soluble proteins referred to above, are precipitated and lost. In order to establish a basis of comparison relative to the composition of natural raw beef juice a number of samples were prepared under known conditions and submitted to analysis. The results contained in the subjoined table clearly show that meat juices made under known conditions vary according to the mode of preparation, but it is evident that practically one-half of the nitrogen is present as coagulable protein.

[2] Bull. No. 21, U. S. Dept. Agricult., Office of Experiment Stations.

FOOD VALUES

In order to arrive at the food value of any commodity it is necessary to consider its chemical composition, available potential energy, absorbability, etc. On referring to the analytical table it will be found that the amount of inorganic material in meat juices Nos. 7 and 10 is unduly high. It appears that sodium chlorid, *per se*, has been added to both Bovinine and Wyeth's Beef Juice probably as a preservative in the latter and for condimental purposes in the former. The relative and absolute proportions of phosphatic material in both products is excessive. The other constituents present in the ash are those usually found in meat products.

The amount of sugar and glycerin in Carnine is interesting. These agents may be added for preserving purposes but the resulting product, on account of its syrupy appearance, leads to the belief and is so represented, that it is a concentrated food. Glycerin is also present in Bovinine and Valentine's meat juice. Bovinine in addition contains about 8 per cent. alcohol.

The total nitrogen content of the trade products excepting Carnine, is greater than the amount of nitrogen present in meat juices proper, but the relative amount of nitrogen present as coagulable protein—the valuable part of meat juice—is much greater in the latter. In fact, the amount of coagulable protein present in Valentine's Meat Juice may be considered *nil*, which indicates that an unduly high temperature is used in its preparation. In this connection it should also be noted that even a moderate elevation of temperature influences the chemical composition of meat juices. For example, the coagulable matter present in Nos. 3, 4 and 5, is approximately one-half that present in Nos. 1 and 2, which appears to indicate that the best product can be made without the use of any heat whatever. Several of the trade products, namely Nos. 7, 8 and 9, contain about as much coagulable material as meat juice made by heating beef to 60 C. According to the formula appearing in a circular of the Bovinine Company, a part of the coagulable matter is present in the form of egg albumin, but the company claims egg albumin is not used at present. In the case of Carnine, the coagulable matter appears to be introduced by the use of blood itself. The exact nature of the coagulable protein matter in Wyeth's Beef Juice has not been ascertained. It is well-known to manufacturers and physiologic chemists that it is practically impossible to manufacture a genuine meat juice possessing a reasonable amount of coagulable proteins, which is stable without a preservative.

Meat juices, in addition to the coagulable protein material, contain other protein bodies such as albumoses and peptones. These bodies are largely formed from the original protein bodies present in the meat juice during the process of manufacture. They are highly nutritious and largely and readily absorbed from the alimentary canal but the amount of these bodies present in the trade products is relatively small excepting in Bovinine, which is not a meat juice, particularly when the high prices are considered.

A considerable proportion of the nitrogenous matter contained in Valentine's and Wyeth's products is present in the form of amino bodies frequently included in the general term, "extractives." These bodies may be oxidized in the body and thus supply heat in a manner similar to alcohol, but it should be remembered that there still appears to be a wide difference of opinion among various observers on this point. Some appear to be of the opinion that the amino bodies are devoid of food value in that these bodies appear in the urine practically unchanged. It would, therefore, appear that the value of the amino bodies is largely of a stimulant character.

The food value of meat juices, therefore, resides largely, if not solely, in the coagulable and other protein material present. Comparing the calorific value or potential energy available in meat juices proper on this basis with that present in the commercial products, excluding Bovinine, it will be seen that on the average the genuine meat juices—that is, those made by pressure, direct from the meat itself as wanted—are much superior to the commercial products, notwithstanding the marked concentration in some cases. The calories given in the accompanying table do not include sugar, alcohol or any other added material of this character.

WYETH'S BEEF JUICE

"Wyeth's Beef Juice" is not a true beef juice, but resembles rather a diluted meat extract. It contains much added inorganic matter, is low in coagulable proteins, and considering the degree of concentration, relatively deficient in nutritive value. Some of the claims contained in the circular accompanying this preparation, in view of its composition set forth above, may be of interest:

COMPOSITION OF MEAT JUICES

Number.		Name of Preparation.	Volatile matter 100 C.	Inorganic matter.	Sodium chlorid.	Phosphoric pentoxid (P_2O_5).	Ether extract, Glycerol and undetermined matter.	Total nitrogen. 10		Meat Juice, M. J. Valentine, Richmond, Va	57.64	10.26	1.77	3.41	20.41^7	3.06^2	.19	5 44	6.06	135.12	16.97

1. Including .20 per cent. as NH_3; 2, including .22 per cent. NH_3; 3, 8.17 per cent alcohol found; 4, vacuum 70 C.; 5, 3.1 per cent. glycerol found; 6, 47.50 per cent. cane sugar—14.2 per cent glycerol found; 7, 8 per cent. of glycerol found.

The several samples of beef juice were prepared from practically fat free, finely comminuted, chuck and round beef, first by pressure at the ordinary temperature; second, by heating the prepared meat for several hours at 60 C., then submitting to pressure. Sample No. 6 was made from chuck beef, prepared as above, by heating six hours at from 60 to 100 C., and expressing after cooling. It is not a beef juice proper but was prepared, analyzed and added to the list for information. Its composition resembles several commercial articles closely. A number of products represented and sold as meat juice in the United States were analyzed and the results recorded in the accompanying table.

1. Including .20 per cent. as NH_3; 2, including .22 per cent. NH_3; 3, 8.17 per cent alcohol found; 4, vacuum 70 C.; 5, 3.1 per cent. glycerol found; 6, 47.50 per cent. cane sugar—14.2 per cent glycerol found; 7, 8 per cent. of glycerol found.

The several samples of beef juice were prepared from practically fat free, finely comminuted, chuck and round beef, first by pressure at the ordinary temperature; second, by heating the prepared meat for several hours at 60 C., then submitting to pressure. Sample No. 6 was made from chuck beef, prepared as above, by heating six hours at from 60 to 100 C., and expressing after cooling. It is not a beef juice proper but was prepared, analyzed and added to the list for information. Its composition resembles several commercial articles closely. A number of products represented and sold as meat juice in the United States were analyzed and the results recorded in the accompanying table.

> "Wyeth's Beef Juice . . . , containing two fluid ounces and representing three pounds of prime lean beef, . . ."
>
> ". . . beef extracts made by the Liebig process are utterly devoid of the valuable and nutritious albuminous constituents of meat, . . ."
>
> [Wyeth's Beef Juice] "should not be compared with ordinary beef extract, . . ."

BOVININE

Bovinine, advertised as a "condensed beef juice prepared by a cold process" is a mixture of alcohol, glycerin, added sodium chlorid, and apparently some form of defibrinated blood. According to the manufacturer's literature egg albumin was used formerly but this ingredient is said to be no longer employed. It is not a meat juice in any sense of the word. Numerous misrepresentations will be found on the label and in the literature of Bovinine, of which the following are typical:

> "The blood of selected steers prepared by a cold process, furnishing a perfect food, free from insoluble elements."
>
> "The rapidity with which Bovinine is absorbed and assimilated in the stomach . . ."
>
> "It supplies complete nutrition to the patient."
>
> "Bovinine contains all the elements of the animal, vegetable and mineral kingdoms for the production of new blood with great rapidity. Its principal constituents have been selected with a view to furnish the largest amount of nutriment in the most condensed form and all the resources of modern chemical analysis have been *brought to bear on this important problem.*"

A series of experiments carried out with dogs under anesthesia, by injecting Bovinine into the stomach, the pyloric end of which was ligated, shows that Bovinine is not readily absorbed and assimilated by the stomach as claimed. The amount of protein material found in the stomach at the end of one-half hour to one hour and a quarter was practically equal to the amount introduced by the Bovinine.

It is also represented that Bovinine is of great service in case of an irritable stomach. This is not borne out by experiment. Bovinine fed to dogs by the mouth, either alone or mixed with food, induced vomiting, which was less marked when Bovinine was given with the regular diet. An examination of the urine of these animals showed a marked diminution of the amount of indican, while the ethereal sulphates were enormously increased, both absolutely and relatively, when Bovinine was given. Experiments on rabbits have shown that Bovinine injected into the peritoneal cavity was invariably followed by large quantities of albumin in the urine, which persisted for from 24 to 48 hours. Thirty to 50 c.c. per kilo given by mouth daily caused emaciation and weakness; in some cases, *irritation of the gastrointestinal canal, with death* of the animal in from 7 to 12 days.

CARNINE

Carnine is a French preparation imported into the United States by Fougera & Co., of New York City. In physical appearace it looks like highly concentrated food, but analysis shows that it consists of a small proportion of defibrinated blood dissolved in a mixture of syrup and glycerol, the whole agreeably flavored. It is represented as a "juice of rare meat, prepared by cold process. Each tablespoonful represents 100 gm. of raw meat, or 3½ ounces." It is clear that Carnine is not a meat juice in any sense of the word.

VALENTINE'S MEAT JUICE

Valentine's Meat Juice resembles in physical appearance taste, odor and by chemical analysis a diluted meat extract. The nutritive value of meat extracts is virtually *nil*, as is well-known by the medical profession. Notwithstanding the composition of Valentine's Meat Juice and the fact that beef extract represents little nutritive value, the manufacturer makes the following misleading representations:

> "The two-ounce oval bottle, adopted for the Meat Juice contains the concentrated juice of four pounds of the best beef, exclusive of fat; or the *condensed* essence of one and a half pints of pure liquid juice which is obtained from the flesh of beef."
>
> "The use of *hot water* with the Meat Juice *changes its character and impairs its value.*" [Italics in original.—Ed.]

The company must certainly be aware of the fact that its product contains little, if any, coagulable proteids.

CONCLUSIONS

In conclusion; neither Bovinine nor Carnine is a meat juice, the former is anything but palatable and the latter soon cloys. "Valentine's Meat Juice" and "*Wyeth's Beef Juice*" are *virtually diluted meat extracts* which are known to possess little food value. A physician depending on any of the foregoing products to supply material nourishment, in case of serious illness, is deceiving himself, starving his patients, and may be lessening their chances for recovery. If a patient recovers while using these commodities, it is certainly not due to the food value contained in them.

ENTERONOL

An Invitation to The Journal to Humbug the Profession

The Journal has received a circular letter from the Enteronol Company, in which the following liberal offer is made:

> "We are willing to take one-fourth or one-half page 'ad' in your Journal for a year at the regular rate, on condition that you accept payment therefore in our GUARANTEED 7 per cent., preferred stock at par; or if you desire, in ENTERONOL at the net wholesale price to physicians."

Not that this offer is made exclusively to The Journal:

> "A large number of medical journals have accepted the foregoing proposition; many carrying this advertising for several years already."
>
> "Our company is cooperative; we paying no cash for advertising. The company is owned principally by physicians, medical journals, and druggists."

The journals of which we have record that carry the enteronol advertisement are: *Kansas City Medical Record, Milwaukee Medical Journal, Toledo Medical and Surgical Reporter, Proctologist, Pediatrics*, and the *Atlanta Journal-Record of Medicine*. If the statements made by the Enteronol Co. are true, we might infer that these journals are being paid for advertising space either with "preferred stock" or *with the* nostrum itself. As we have previously shown, however, the veracity of the enteronol advertising matter is by no means unimpeachable.

Enteronol, it will be remembered, was exposed in The Journal, March 21, 1908. It is advertised as the "greatest antiseptic and germicide known to science," and possesses (?) such remarkable power that it "destroys the germs of typhoid fever, acute and chronic diarrhea, dysentery, cholera infantum, cholera morbus, summer complaint, Asiatic cholera, etc., within two hours." "The original product is found only high up on the sides of the loftiest mountains in the world—the *Himalayas of India.*"

THE "LITERATURE" FORMULA

Of course it has a "formula":

Ipecac
Sub. nit. bismuth
Latalia rad.
Camphor
Lupulin
Caffein
Rheum

This seems very open and above board, except as to quantities, until one tries to find out what "latalia rad." is; then it is discovered that it is the "mysterious stranger" of pharmacognosy. Experts to whom this "remedy" was submitted were unable even to find mention of such a drug or plant as "latalia rad." Nor was this the only fake found concerning the stuff; carefully conducted experiments repeatedly carried out in the Association's laboratory failed to disclose even a trace of bismuth subnitrate or caffein. These experiments did show, however, that the tablets contained an amount of aluminum corresponding to over 25 per cent. of crystallized alum. This led to the conclusion that alum, whose presence is not even hinted at in the "formula," is the chief constituent of enteronol and as a corollary that the formula is meaningless and worthless.

THE LABEL FORMULA

There is a curious lack of coordination between the "formula" *as printed on the label and that given in the "literature."* The Food and Drugs Act, it will be remembered, makes lying on the label illegal, and therefore dangerous; statements in advertising matter that does not accompany the product, however, are not controlled by that law. The "formula" in the "literature" we have already given; the "formula" on the label gives the following ingredients:

Ipecac
Sub. nit. bismuth
Opium, ¼ gr.
Camphor
Lupulin
Caffein
Rheum

Two things about this are worth noting: One is that the name of the ingredient on which the manufacturer lays so much stress—latalia rad., the mysterious Himalayan plant—is absent from the label. This would seem to indicate that what has already been intimated by The Journal—namely, that latalia rad. is a figment of the imagination—is a fact. The second noticeable thing about the label "formula," as distinct from the "formula" in the advertising matter, is that on the label we find there is opium in the preparation. Why is no mention made of the presence of this potent drug in the advertising matter?

To determine how nearly the present statements made by the Enteronol Company approximate truthfulness, our chemists were asked to examine the nostrum as it is now sold. Their report follows:

LABORATORY FINDINGS

An original package of enteronol tablets was purchased on the open market and submitted to the Association laboratory for examination. In general appearance, odor and taste the new tablets are similar to those previously examined. The formula for the old tablets was given as "Ipecac, Sub. nit. bismuth, Latalia rad., Camphor, Lupulin, Caffein, Rheum," and is still used in the circulars. But the label on the trade package no longer mentions "latalia rad." Since the presence of "latalia rad." in the old tablets, was questioned, and as new labels have ceased to display the name, it was thought possible that caffein and bismuth might now be constituents of enteronol, as the drugs are still mentioned in the new formula on the label. Accordingly, enteronol was examined chemically to verify the statements on the label regarding the presence of caffein and bismuth in the tablets.

The specimen submitted to the laboratory some time ago was found to contain neither bismuth nor caffein. By employing the same methods as were used before (the usual tests for detecting caffein and bismuth), neither caffein nor bismuth could be demonstrated. It is thus evident that this new specimen of enteronol, the statement on the label to the contrary notwithstanding, contains neither bismuth nor caffein—at least, in appreciable quantities.

One would think that the discrepancy between "formulas" and facts would prove of interest to the stockholders of the Enteronol Company, especially as we are told that the policy of the company is to have "practical men as stockholders." We are informed:

> "Therefore, we have physicians, advertising experts, printers, publishers, engravers, boxmakers, lithographers, druggists, lawyers, traveling salesmen, officers and men holding executive positions in various manufacturing and commercial corporations, editors of medical publications, bishops, clergymen and missionaries—men from all the fields particularly valuable commercially for our great enterprise."

Yet if the physician-stockholders do not care to concern themselves about the composition of the nostrum from the sale of which they derive dividends, it can hardly be expected that the boxmakers or traveling salesmen will be interested.

STOCK FOR SALE

Medical journals are not alone in being invited to participate in the exploitation of this nostrum, *vide* a circular letter from the Enteronol Company addressed "To Investors":

> "We offer at par of $10 each, 1,000 shares of our Guaranteed 7 per cent. Preferred Stock, cumulative dividends, payable quarterly . . . Profits on business done last year were 54 cents for every dollar expended . . . *We guarantee absolute security for your investment. Safer than a bank.*" [Italics ours.—Ed.]

We are told that at present the Enteronol Company manufactures two products: a castor-oil preparation, known as fig-ol, and enteronol. Very shortly, however, the company expects to "add seven equally efficient products."

> "The average cost to manufacture, ready to ship, a dollar's worth of these goods is less than ten cents."

> "In enteronol alone, the company has fortunes and the only thing needed to bring tremendous results and dividends of 100 per cent. is the proper amount of judicious advertising."

Here are some samples of the judicious (?) advertising:

> "One Christian missionary, the Rev. Paul Singh of Jubbulpore, India, testifies that he cured thirteen severe cases of Asiatic Cholera with a box containing less than thirty tablets" [of enteronol].

> "Wm. F. Oldham, bishop of Southern Asia, writes us that enteronol cured nine cases out of ten of Asiatic Cholera. Now just think of India and China with their 800,000,000 people who are dying by the thousands of a disease which we have the power to cure so easily."

How like a discourse by that delightful character of Mark Twain's—the visionary Colonel Sellers—this reads. As he said about his "Infallible, Imperial, Oriental Optic Liniment:"

> "Why in the Oriental countries . . . every square mile of ground upholds its thousands on thousands of struggling, human creatures—and every separate and individual devil of them's got the ophthalmia."

The prospective stockholder is told that an ordinary business concern reaches the limit of financial possibilities in a few years, but:

> "Not so with the Enteronol company—it is a mail-order business and the world is its territory."

Even so with Colonel Seller's "Optic Liniment:"

> " . . . It's a patent medicine whose field of operations is the solid earth."

And we are told elsewhere that "about four-fifths of the outstanding stock is held by the medical profession alone"!

And this stuff is advertised in medical journals!!

We are sometimes in danger of being too optimistic regarding the results of the propaganda for reform in proprietary medicines. Cases like this act as a corrective.

Correspondence

Eye Changes in Pellagra—Credit to Dr. Welton

To the Editor: In going over the report of the Conference on Pellagra at Columbia, S. C., November 3 and 4 (The Journal, November 13), I find that the reporter has given me credit for some conclusions which should rightly be credited to Dr. Carroll B. Welton of Peoria, Ill., namely, in the report of my paper (page 1661), that portion beginning, "Paralysis of the eye muscles is found in the later stage of the disease," and ending, "The finding of marked eye changes adds to the gravity of the prognosis in pellagra and indicates, in a large percentage of cases, an early fatal termination." These conclusions were quoted as a matter of general interest, due credit being given Dr. Welton, from a paper by him which appears in the same issue of The Journal, page 1636. I very much regret we have been put in this false position.

J. F. Siler, Captain Medical Corps, U. S. Army.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

EOSINOPHILIA: ITS CAUSE AND SIGNIFICANCE: LITERATURE

To the Editor:—What is the most generally accepted view regarding the cause and significance of eosinophilia? Please refer me to the most recent literature on the subject R. L. S.

Answer.—Eosinophilia is apparently due to the entrance of some toxin into the blood but the nature of the exciting cause is not certainly known. Infections are usually accompanied by a relative or absolute decrease of eosinophiles. Exceptions are seen in scarlatina and malaria. Malignant diseases seldom show eosinophilia. Affections of the genitals are accompanied by eosinophilia. It is found in myeloid leucemia and in bronchial asthma, especially in the sputum. Eosinophilia is likely to occur in any case in which intestinal worms are present, particularly in uncinariasis and trichiniasis. The discovery of eosinophilia is of service in the diagnosis of helminthiasis, in distinguishing non-malignant from malignant disease of the viscera, etc. It tends to make the prognosis favorable in scarlatina, chlorosis, pernicious anemia, and after hemorrhage.

Following are titles of some of the most recent articles on the subject:

REFRACTION FOR GENERAL PRACTITIONERS

To the Editor:—Please tell me where I can obtain a short or condensed work on simple refraction for family physicians or general practitioners, as I think every physician should be qualified to do refraction work. J. B. Dillon, M.D., Paragould, Ark.

Answer.—One of the best works is Thorington's treatise on the refraction of the eye. The subject is also satisfactorily treated in a number of ophthalmic text-books, such as Jackson's "Diseases of the Eye," Wood and Woodruff's "Commoner Diseases of the Eye," etc. It must not be assumed that even the elements of the "fitting of glasses" can be learned by the reading of any book, however earnestly pursued. Even the rudiments of practical refraction work, like the practice of auscultation, or cystoscopy or urinalysis, call for something more than mere literary knowledge. Indeed, the most important part of lens prescription consists in the use of mechanical appliances whose successful employment requires considerable practice with the aid and under the eye of a competent instructor. Unless one has obtained this practical instruction during one's college career it would be necessary to spend a month or longer in securing it before one could conscientiously undertake to prescribe glasses. The physician's education gives him a decided advantage over the optician and the "optometrist" in this work. It should be realized, however, that only painstaking and intelligent work will enable the physician to compete successfully with those who "examine eyes free." His eventual aim should be to consider, not only how to measure refractive errors, but, as a part of this work, to determine the balance of the eye muscles, the state of the ocular fundi (by the use of the ophthalmoscope) the condition of the anterior parts of the eye and, finally, to decide to what extent, if any, the neighboring organs and the general health are responsible for the ocular symptoms. These the physician would be able to do, while the optometrist could not. In other words, in doing this work the practitioner will find his collegiate training of decided value. He ought, with an equal amount of study and application, to make a much better and more effective refractionist than his competitor, the "doctor of optometry," who is really attempting to solve, without a medical education, problems that are essentially medical.

The Public Service

Medical Department of the Army

Changes for the week ended Nov. 13, 1909.

Murtaugh, J. A., capt., ordered to report at San Francisco, for examination for promotion.

Christie, A. C., Johnson, H. H., and Gostin, B. S., 1st lieuts., relieved from duty in the Philippines Division; will sail January 15, for San Francisco.

Kennedy, J. M., major, ordered to take temporary charge of the office of the Chief Surgeon, Dept. of California.

Webber, H. A., major, granted leave of absence for 2 months.

Dear, W. R., Wright, F. S., Treuholtz, C. A., Dunbar, L. R., and Davis, A. D., 1st lieuts., relieved from duty at their present stations; will proceed to San Francisco, and sail January 5, for Philippine service.

Wallace, G. S., 1st lieut., M. R. C., granted leave of absence for 14 days.

Jarrett, A. R., 1st lieut., M. R. C., relieved from duty at Fort Hamilton, N. Y.; will proceed home and then stand relieved from active duty in the Medical Reserve Corps.

Merrick, J. N., and Jenkins, F. E., 1st lieuts, M. R. C., relieved from duty in the Philippines Division; will sail January 15, for San Francisco.

Scott, H. O., dental surgeon, granted leave of absence for 2 months, on arrival in the United States.

Craig, E. J., dental surgeon, relieved from duty at Fort Leavenworth, Kan., and ordered to proceed to his home for annulment of contract.

Public Health and Marine-Hospital Service

Changes for the seven days ended Nov. 10, 1909:

Stoner, G. W., surgeon, granted 7 days' leave of absence from Oct. 30, 1909, under paragraph 189, Service Regulations.

Carter, H. R., surgeon, granted 15 days' leave of absence from November 10, 1909, on account of sickness.

White, J. H., surgeon, granted 4 days' leave of absence en route to station.

McIntosh, W. P., surgeon, granted 10 days' leave of absence from Nov. 10, 1909.

Oakley, J. H., surgeon, granted 1 day's leave of absence, Nov. 5, 1909.

Francis, Edward, P. A. surgeon, detailed as Assistant Director of the Hygienic Laboratory, effective Nov. 5, 1909.

Francis, Edward, P. A. surgeon, directed to proceed to Detroit, Chicago and Milwaukee, on special temporary duty.

Burkhalter, J. T., P. A. surgeon, granted 7 days' leave of absence from Nov. 8, 1909.

McCoy, G. W., P. A. surgeon, directed to proceed to Berkeley, Cal., on special temporary duty.

Creel, R. H., P. A. surgeon, on the arrival of Surgeon W. G. Stimpson, directed to proceed to Baltimore, and report to the medical officer in command for duty and assignment to quarters.

Spratt, R. D., P. A. surgeon, granted 20 days' leave of absence from Nov. 17, 1909.

de Valin, Hugh, P. A. surgeon, granted 1 month's leave of absence from Nov. 10, 1909.

Wollenberg, R. A. C., asst.-surgeon, relieved from duty at Naples, Italy, and temporary duty at Detroit, and directed to proceed to San Francisco, and report to Passed Assistant-Surgeon W. W. King for duty.

Atilles, P. del V., acting asst.-surgeon, leave of absence granted for 30 days from Aug. 18, 1909, with pay, and 15 days from Sept. 17, 1909, without pay, amended to read 30 days from Aug. 23, 1909, with pay, and 2 days from September 23, 1909, without pay.

Mason, W. C., acting asst.-surgeon, granted 5 days' leave of absence from Nov. 18, 1909.

Miranda, R. U. Lange, acting asst.-surgeon, leave of absence granted for 1 month from Oct. 8, 1909, without pay, amended to read 7 days from Oct. 8, 1909, without pay.

Richter, H. C., acting asst.-surgeon, granted 15 days' leave of absence from Oct. 15, 1909.

Terry, M. C., acting asst.-surgeon, leave of absence granted for 21 days from Oct. 1, 1909, with pay, and 9 days from Oct. 22, 1909, without pay, amended to read 21 days from October 2, 1909, with pay, and 2 days from Oct. 23, 1909, without pay.

Health Reports

The following have been reported to the Marine-Hospital Service, during the week ended Nov. 12, 1909:

SMALLPOX—UNITED STATES

Alabama: Mobile, Oct. 17-23, 1 case.
Georgia: Macon, Oct. 16-31, 3 cases.
Illinois: Chicago, Oct. 24-30, 2 cases.
Indiana: Muncie, Oct. 1-31, 9 cases.
Kansas: Labette County, Parsons, Sept. 1-30, 1 case; Scott County, 1 case; Shawnee County, Topeka, 2 cases.
Louisiana: New Orleans, Oct. 1-30, 1 case.
Michigan: Saginaw, Oct. 10-15, 3 cases.
Montana: Dawson County; Sept. 1-30, 2 cases; Silver Bow County, 1 case.
New York: Buffalo, Oct. 24-30, 2 cases.
Ohio: Springfield, Oct. 17-30, 6 cases.
Oregon, general, July 1-31, 21 cases, Aug. 1-31, 15 cases; Portland, Sept. 1-30, 8 cases.
Texas: San Antonio, Oct. 1-30, 1 case.
Utah, general, Sept. 1-30, 59 cases.
Wisconsin: La Crosse, Oct. 24-30, 1 case.

SMALLPOX—FOREIGN

Brazil: Bahia, Sept. 25-Oct. 8, 25 cases, 15 deaths; Pernambuco, Aug. 16-31, 11 deaths; Rio de Janeiro, Sept. 27-Oct. 10, 3 cases.
China: Shanghai, Sept. 25, present among natives.
Great Britain: London, Oct. 3-9, 1 case.
India: Bombay, Sept. 29-Oct. 5, 4 deaths; Madras, Sept. 25-Oct. 1, 2 deaths; Rangoon, Sept. 19-25, 1 death.
Italy, general, Oct. 11-17, 37 cases; Genoa, Oct. 1-15, 1 case; Naples, Oct. 11-17, 4 cases.
Mexico: Medellin, Oct. 18-24, present in vicinity; Monterey, 1 death; Soledad, 3 cases; Veracruz, Oct. 24-26, 10 cases, one case from Orizaba; October 26, 1 case on s. s. *Montevideo.*
Russia: Moscow, Oct. 3-9, 2 cases; Odessa, 12 cases, 5 deaths, Riga, Oct. 3-10, 1 case; Warsaw, Sept. 5-11, 2 cases.
Spain: Almeria, Sept. 1-30, 3 deaths; Barcelona, Oct. 12-18, 4 deaths; Huelva, Sept. 1-30, 14 deaths; Valencia, Oct. 9-16, 1 case; Vigo, 1 death.
Uruguay: Montevideo, Aug. 1-31, 8 deaths.

CHOLERA

Belgium: Boom, Oct. 26-30, 9 cases, 6 deaths, vicinity of Antwerp.
China: Amoy, Sept. 19-25, 22 deaths; Shanghai, Sept. 25, present among natives.

Germany: Andreischen, Nov. 1, 3 cases; Heydekrug, 1 case; Lallan district, 3 cases; Neiderung district; 3 cases.
India: Bombay, Sept. 29-Oct. 5, 6 deaths; Rangoon, Sept. 12-25, 10 deaths.
Java: Batavia, Sept. 12-25, 200 cases, 100 deaths.
Russia: St. Petersburg, Oct. 9-15, 266 cases, 111 deaths; Moscow, Oct. 3-9, 1 death; Riga, Oct. 10-16, 4 cases, 2 deaths.

YELLOW FEVER

Brazil: Para, Oct. 9-16, 4 cases, 2 deaths; Pernambuco, Aug. 16-31, 1 death.
Mexico: Merida, Oct. 20-21, 2 cases, 1 death.

PLAGUE—UNITED STATES

California: Contra Costa County, Oakland, Oct. 26, 1 case.

PLAGUE—FOREIGN

Brazil: Bahia, Sept. 25-Oct. 8, 18 cases, 13 deaths; Rio de Janeiro, Oct. 3-10, 1 case.
China: Amoy, Sept. 19-25, 38 deaths.
Japan: Kobe, Sept. 26-Oct. 2, 7 cases, 3 deaths.
India, general, Sept. 19-25, 4,650 cases, 3,595 deaths; Bombay, Sept. 29-Oct. 5, 15 deaths; Rangoon, Sept. 12-25, 5 deaths.

Marriages

Sir Wilfred Thomason Grenfell, M.D., Battle Harbor, Labrador, to Miss Anna MacClannahan of Chicago, November 18.

Eugene Albert Smith, M.D., Milwaukee, Wis., to Miss Daisy Arloine Lamoreaux of St. James, Minn., November 4.

Arthur Harris Johnson, M.D., Greensboro, N. C., to Miss America Seay, at the Shores, Virginia, November 2.

Robert Thrift Ferguson, M.D., Gaffney, S. C., to Miss Mary Steele Parrish, at Richmond, Va., November 2.

W. Elton McWhirt, M.D., Globe, Ariz., to Miss Maude Estelle Sherrick of Libertyville, Iowa, November 4.

Robert Henry Stephens, M.D., Treynor, Iowa, to Miss Margaret Ward of Council Bluffs, Iowa, November 4.

Charles Freeman Starr, M.D., Mason City, Iowa, to Miss Alma Taylor of Emmetsburg, Iowa, October 28.

William Sebald Keller, M.D., Cincinnati, to Miss Harriette Richardson of Glendale, Ohio, October 26.

Daniel Alden Barrell, M.D., to Miss Martha Louise McFarland, both of Auburn, Maine, November 5.

Christian P. Glahn, M.D., Palmyra, Mo., to Miss Nellie G. Holman of Hurdland, Mo., November 3.

Walter Freeman Brown, M.D., to Miss Mabelle Stewart Moore., both of Philadelphia, October 21.

Walter W. Covell, M.D., Brownlee, Neb., to Miss Martha B. Lund of Kearney, Neb., September 29.

Ralph Vernon Moore, M.D., Amboy, Ill., to Miss Catherine Sheridan of Freeport, Ill., November 3.

James Herbert Young, M.D., Newton, Mass., to Miss Irene Hamilton of Newark, N. J., October 28.

Charles P. Feeley, M.D., to Miss Matilda A. Sennott, both of Cambridge, Mass., November 2.

Robert J. Gregg, M.D., to Mrs. Gertrude H. Moorehouse, both of Dulzura, Cal., recently.

Robert Irving Bullard, M.D., to Miss Ellen Merriman, both of Springfield, Ill., November 4.

Deaths

Marcus Patten Hatfield, M.D. Chicago Medical College, 1872; for many years a member of the American Medical Association; professor of diseases of children in Chicago Medical College from 1875 to 1896; since 1898 professor of pediatrics in the Chicago Clinical School; clinical professor of pediatrics in the Medical Department of the University of Illinois; president of the medical board of La Rabida, the Jackson Park Fresh Air Sanitarium; attending physician to the children's department of Wesley Hospital and Chicago Protestant Orphan Asylum; author of several works on the diseases of children and hygiene and editor of the *Chicago Clinic*; died at his home, November 11, from tuberculosis, aged 60.

John Harvey Davisson, M.D. College of Physicians and Surgeons, Baltimore, 1876, and Cathell gold medalist of his class; a member of the American Medical Association; one of the organizers of the Southern California Medical Society and of the California Hospital Association; formerly president of the California State Board of Health; for four terms a member of the Los Angeles Board of Health; formerly professor of physiology and materia medica in the Fort Wayne (Ind.) College of Medicine; local surgeon at Warsaw to the Pennsylvania System, and secretary of the Surgeons' Association of the Pennsylvania Railway; died at his home in Los Angeles, November 1, from nephritis, aged 60.

Gabriel Grant, M.D. College of Physicians and Surgeons, New York City, 1850; a member of the American Medical Association; in 1852 a practitioner on the Isthmus of Panama; afterward health commissioner of Newark, N. J.; surgeon of the Second New Jersey Volunteer Infantry for more than three years during the Civil War, until forced to retire on account of a wound received in battle; died at his home in New York City, November 8, aged 83.

Augustus F. Anderson, M. D. Medical College of Georgia, Augusta, 1845; a member of the Medical Association of Georgia; assistant surgeon of the Sixth South Carolina Infantry, C. S. A., during the Civil War and for a number of years thereafter a member of the local pension board; a member of the legislature in 1878; died at his home near Lowryville, S. C., November 1, from heart disease, aged 91.

Aaron W. Riker, M.D. Albany (N. Y.) Medical College, 1856; president of the village of Fenton, Mich., for several terms a member of the village council, and for twenty years a member of the school board; for many years district surgeon for the Detroit, Grand Haven and Milwaukee Railway; died at his home in Fenton, October 31, from fatty degeneration of the heart, aged 78.

William M. McQuerry, M.D. Transylvania University, Lexington, Ky., for more than forty years a practitioner of Texas; a member of the State Medical Association of Texas, and a charter member of the Brown County Medical Society; a lieutenant in the Confederate service throughout the Civil War; died at his home in Zephyr, September 24, aged 76.

William Kirker Coleman, M.D. Medical College of Ohio, Cincinnati, 1881; a member of the American Medical Association, and a member of the local pension examining board; president of the Adams County (Ohio) Bank; and until recently superintendent of the State Hospital for Epileptics, Gallipolis; died at his home in West Union, November 5, aged 56.

Edward Taylor M. Rickard, M.D. Lincoln (Neb.) Medical College, 1897; College of Physicians and Surgeons, Chicago, 1906; of Weeping Water, Neb.; a member of the American Medical Association; while making a professional call near Weeping Water, November 8, was instantly killed by being crushed under his overturned automobile, aged 46.

Henry Palmer, M.D. University of Michigan, Ann Arbor, 1887; formerly a member of the Michigan State Medical Society; for several terms mayor of St. Johns, and health officer and supervisor of Clinton county; a member of the local pension board; died at his home in St. Johns, November 2, from diabetes, aged 52.

Robert W. Chapman, M.D. Kentucky School of Medicine, Louisville, 1886; a member of the State Medical Association of Texas and a practitioner since 1882; for several years a member of the medical examining board of the Second Judicial District of Texas; in 1895 elected state representative, and re-elected in 1907; died at his home in Geneva, January 4, aged 49.

Charles Frederick George, M.D. College of Physicians and Surgeons, New York City, 1865; a member of the New Hampshire Medical Society; associate physician at the Eliot Hospital, Manchester; died suddenly at his home in Goffstown, November 3, from cerebral hemorrhage, aged 68.

Luther A. Davison, M.D. New York University, New York City, 1882; of Hartford; a member of the Connecticut State Medical Society; while returning after making a professional call, November 1, had a cerebral hemorrhage, and died at the Hartford Hospital, aged 60.

Edward Aubert Besson, M.D. College of Physicians and Surgeons, San Francisco, 1900; a member of the American Medical Association; visiting physician at the French Hospital, San Francisco; died at his home in that city, November 4, aged 42.

Samuel D. Robbins, M.D. Tulane University, New Orleans, La., 1876; formerly acting assistant surgeon United States Marine Hospital Service at Vicksburg, Miss.; founder of the Mississippi State Charity Hospital; died in Vicksburg, November 4.

George C. Waiss, M.D. Rush Medical College, Chicago, 1894; a member of the American Medical Association; consulting gynecologist to the Hospital of St. Anthony of Padua; died at his home in Chicago, November 11, from appendicitis, aged 42.

Valentine Braun, M.D. Starling Medical College, Columbus, Ohio, 1853; a member of the Toledo school board and council, and in 1865 treasurer of Lucas County; died at the home of his niece in Toledo, October 19, from senile debility, aged 80.

William D. Ray, M.D. Tulane University, New Orleans, La., 1892; a member of the State Medical Association of Texas; local surgeon of the Southern Pacific Railroad at East Bernard for ten years; died at his home, September 26, aged 58.

Samuel Moses Post, M.D. University of Michigan, Ann Arbor, 1871; a member of the Michigan State Medical Society; a member of the local pension board; died suddenly at his home in St. Johns, November 6, from heart disease, aged 61.

Franklin B. Ives, M.D. Rush Medical College, Chicago, 1850; a practitioner and clergyman of Bureau County, Ill., for many years, and later a resident of California; died at his home in Long Beach, November 1, from senile debility, aged 86.

Andrew Franklin Brown, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1859; formerly of Laddonia, Mo.; president of the Citizens' Bank, Wentzville, Mo.; died at his home in that place, October 10, from gastritis, aged 70.

James Franklin Davis, M.D. Jefferson Medical College, Philadelphia, 1859; of Clinton, S. C.; a surgeon in the Confederate service during the Civil War; died at the home of his cousin, near Clinton, November 4, aged 74.

Edward Joseph Hogan, M.D. College of Physicians and Surgeons, New York City, 1867; a member of the American Medical Association; died at his home in New York City, November 7, from heart disease, aged 72.

Sylvester M. King, M.D. Hahnemann Medical College, Chicago, 1878; for many years a member of the local pension board of Monroe County, Iowa; died at his home in Albia, November 1, from pneumonia, aged 73.

Jacob Hamaker Drawbaugh, M.D. College of Physicians and Surgeons Baltimore, 1886; a member of the American Medical Association; died at his home in Shiremanstown, Pa., September 4, from tuberculosis, aged 50.

Charles Henry Burnham, M.D. Medical School of Maine, Brunswick, 1866; a member of the New Hampshire Medical Society; died at his home in Jefferson, N. H., November 3, from cerebral hemorrhage, aged 66.

Sarah Jane Williams, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1871; city physician of Springfield, Mass., in 1872; died in Boston, Sept. 27, 1908, from general paralysis, aged about 69.

Lathrop Russell Charter, M.D. Castleton (Vt.) Medical College, 1841; a charter member of the West Virginia State Medical Association; died at his home in West Union, September 28, from acute nephritis, aged 92.

Richard H. Rhoden, M.D. Missouri Medical College, St. Louis, 1886; a member of the American Medical Association; surgeon to the Fremont (Neb.) Hospital; died at his home in Fremont, October 30, aged 47.

Styles M. Taylor, M.D. Memphis (Tenn.) Hospital Medical College, 1892; for twenty-seven years a practitioner of Texas; died at his home in Yale, near Mount Vernon, September 10, from typhoid fever, aged 55.

Morris Lewis Davis, M.D. Starling Medical College, Columbus. Ohio, 1879; New York University, New York City, 1884; died at his home in Agency, Iowa, May 21, 1908, from gastric ulcer, aged 63.

Bert Jerome Longwell, M.D. University of Nashville (Tenn.), 1903; of Wheeling, W. Va.; died in St. Joseph's Hospital, Logansport, Ind., October 20, from nephritis, aged 36.

James F. Irvin, M.D. University of Pennsylvania, Philadelphia, 1853; died at his home in Des Moines, September 25, from cerebral hemorrhage, aged 80.

L. Joseph Struzynski, M.D. University of Dorpat, Russia, 1850; died at his home in Joliet, Ill., November 5, from senile debility, aged 86.

Silas James Chesebrough, M.D. Albany (N. Y.) Medical College, 1844; is reported to be dead at his home in Syracuse, N. Y.

Lemier Congdon, M.D. University of Buffalo (N. Y.), 1852; died in his rooms in Springfield, Mass., November 4, aged 74.

MEDICAL ORGANIZATION IN VERMONT AND NEW HAMPSHIRE

By J. N. McCormack, M.D.
Chairman of the Committee on Organization
BOWLING GREEN, KY.

I have never had a more delightful experience, or come in contact with a more cultivated profession and people, than during the sixteen days' itinerary in Vermont and New Hampshire. The Green and White Mountain lake and valley regions may have less of grandeur and sublimity than Switzerland, but they rival it in picturesque beauty and excel it in fertility. In fact, but for the lack of the loftiest, snow-capped peaks and glaciers, and the absence of women from the fields and other out-of-door labor, the small valley and hillside farms were so carefully cultivated, the houses, gardens and orchards looked so neat, tasteful and prosperous, and industries of every kind were so varied and profitable that one was constantly reminded of that beautiful and thrifty country. It was in all of its glory, too, in the latter part of September and the beginning of October, with ideal weather most of the time, and the rich coloring of the forests and fields was beyond any power of my pen to describe.

The public meetings were admirably planned and advertised, the suggestions of Dr. Green having been followed in both letter and spirit, and taken one with another, the audiences and discussions were better and more appreciative than in any other section I have visited. Governor Quimby presided at one of the meetings in New Hampshire, U. S. Senator Burnham at another, and congressmen, judges and other leading officials or citizens took an intelligent and often an enthusiastic part in the discussion at each appointment. The standards of education are higher and more general here than in the West and South, and I have found that the people are responsive to reform just in proportion to their intelligence.

Except in Burlington, Concord and a few other places, the medical meetings in the afternoon were not so well arranged or attended. In fact, one could not avoid the impression that there was danger of the public becoming more progressive than the profession in all these matters, just as the pews often seem to lead the pulpit in moral reforms. For instance, at his great marble works a little way out from Rutland, Governor Proctor has provided for his 3,200 employees and their families one of the purest and best protected of water supplies, model schools, churches, a hospital, library, Y. M. C. A. building, and isolation hospital for *consumptives*, in a broad way which might well be held up as an object lesson for employers of labor everywhere, both for its humanitarian and economic advantages. This wise young layman had no doubt obtained much of his first inspiration from Drs. Caverly and Holton and their associates on the State Board of Health, but he had worked out and demonstrated the practical value of health and life in a way that gave me much to think over, as no doubt has been the case with every medical man who comes in touch with his progressive methods. Other instances like this, only a little less conspicuous, might be cited in abundance.

The lack of medical organization, in the sense in which we understand it, and for which I am striving, was as evident as it was unaccountable. Personally and collectively the profession here is of the highest grade and composed of the most cultivated men with whom I have ever come in contact, and I have never found any more warm-hearted and approachable. Their leaders are not better than the leaders of the West and South, but they have a far smaller percentage of low-grade men than are seen elsewhere. This grows out of the facts that it is an older civilization than any other in this country that escaped the ravages of the civil war, that it has more wealth, and better general education, and especially that it never had the multiplication of medical schools and the preponderance of low-grade, cheap schools which have so cursed the West and South until recent years, and which still exist in some sections. Though the individual standard is so high, though the work in the state societies and boards is in the hands of men whose abilities are recognized everywhere, and though the latter have accomplished so much in many lines, I found but one society which meets as often as once a month, most of them meeting quarterly or semiannually, and often with but half or two-thirds of the eligible physicians in the membership. In one of the most important cities in Vermont, one of great historic interest and cultivation, and with a large medical population, the county society meets once a year, when they can get a quorum, which they had not had for two years. In New Hampshire, probably by an oversight, membership in the state society may be retained without joining the county society, a mistake which was made in several other states early in the reorganization movement, and only remedied after it had produced inevitable confusion and discord. The main difficulty seemed to be that even the leaders of the profession had not caught the spirit and purpose of organization, with county societies and weekly or semi-weekly meetings and postgraduate studies as the foundation and main factors in bringing the physicians of each community together, with the opportunity of knowing each other better and ultimately bringing about in our more or less discordant ranks the good fellowship and cooperative spirit which has always existed in the legal profession. Boards of health, medical boards, hospitals, and practical public laboratories are far more important to the people than courts, just in proportion as health and life are more important than any mere property interests, but because lawyers naturally associate with each other in their every-day work, with the breadth and good fellowship resulting therefrom, they have always had a prominence and guiding influence in public affairs, local, state and national, which we have never had, and ought not to have, until we can get together in each county and community and artificially reproduce the harmonious conditions which exist naturally in the legal profession.

The results of lack of organization were in evidence on every hand. Medical fees were surprisingly low, and especially so when the high grade of the profession and the cost of living and equipment are considered, and poverty in the rank and file of the profession exists to an extent not recognized by its leaders or the people. As is my custom, I tested this by careful inquiry in typical counties as to the percentage of physicians who own their homes and are comparatively free from debt at middle life, or who could attend their state and national associations, or go away for a postgraduate course or a vacation, without injustice to their families, and usually found it very small. Discord was as marked and unpleasant in several counties as I have ever found it elsewhere. Christian Science and similar fads flourish; a larger percentage of the cream of the practice seems to have passed out of the hands of the regular profession than in any other part of the country, and there seems no end to this drift unless our profession and especially our schools—still distinctly its least progressive element, in spite of the high character and ability of those comprising the faculties—can be aroused to the importance of occupying the field of psychotherapy, mechanotherapy, and similar therapies in such a scientific way as will leave no place for faddists and quacks. I have found no other profession more responsive to appeals for better things than that here, or more capable of doing them, and as they at once took up the postgraduate work, the plans for frequent public meetings and other progressive methods in almost every county, I shall be disappointed if most excellent results do not follow.

My thanks are due to Drs. Beecher and Sullivan, secretaries of the Vermont and New Hampshire state societies, respectively, and to the local committees having the meetings in charge at each appointment for arrangements which were so complete as to leave nothing to be desired, and to both the profession and people for a reception and for hospitality as cordial and charming as it was constant.

Bismarck, N. D., Nov. 6, 1909.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Third Month—Fourth Weekly Meeting

Chicken-Pox, Varicella

Etiology: Contagiousness, age, transmission, incubation.
Symptoms.
Diagnosis: Differentiate from smallpox, impetigo contagiosa.

Acute Infectious Diseases Accompanied at Times by Eruptions

Typhoid Fever: Characteristic rash. Erythema, urticaria, herpes, sudamina, desquamation after typhoid.
Typhus Fever: Characteristic petechial eruption.
Influenza: Erythema, urticaria, herpes, sudamina.
Dengue: Primary and secondary exanthemata.
Malaria: Herpes, erythema, urticaria, purpura, pigmentation.
Epidemic Cerebrospinal Meningitis: Characteristic petechial rash, herpes.
Rheumatic Fever: Sudamina, erythema purpura, erythema nodosum.
Serum Eruptions: Frequency. Date of appearance. Character of eruption, urticarial, erythematous, vesicular, petechial. Distribution of rash.

Monthly Meeting

Differential Diagnosis of Smallpox.
Bacteriology of Scarlet Fever, of Smallpox.
Prevention of the Spread of the Exanthemata; Vaccination and Quarantine; Treatment of the Patient; Disinfection.

Society Proceedings

COMING MEETINGS

American Physiological Society, Boston, December 28-30.
Southern Surg. & Gynecological Assn., Hot Springs, Va., Dec. 20-21

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirty-seventh Annual Meeting, held at Richmond, Va., Oct. 19-22, 1909

The President, Dr. Gardner T. Swarts, Providence, R. I., in the Chair

The officers elected were given in The Journal, Nov. 6, 1909, p. 1573.

Second Decennial Revision of International Classification of Causes of Death

Dr. Cressy L. Wilbur, Washington, D. C.: The second decennial revision of International Classification of Causes of Death is the most important event that has occurred affecting vital statistics during the past year, and the possibility of twenty-three nations joining in this revision reflects much credit on the American Public Health Association. We are at the beginning of a great undertaking, namely, the preparation of a national nomenclature of diseases and causes of death. I believe that the most important practical measure which can come up for consideration next year will be the preparation of a series of uniform statistical tables relating to births, stillbirths, deaths, sickness, marriages, and divorces for use in the federal, state and municipal reports and bulletins. It has been largely a matter of speculation to know whether the figures taken from different reports were comparable or not. I would propose to the officers of the association and also members of the council of the section on vital statistics that they cooperate by the appointment of special committees, whose work can be aided by the Bureau of the Census in the preparation of uniform tables to be used in registration reports.

A complete agreement was had as to the form of questions for the cause of death. The note on the face of the blank is as follows: "State the disease causing death, or in deaths from violent causes, state first the means of injury; second, whether accidental, suicidal or homicidal." As to the changes from the previous classification, I have been notified that

Census Bulletin No. 104 has been printed and two copies have been sent to me. This contains the title of the classification, and each title which has not been changed or modified from the former series is noted by an asterisk.

Management of Milk-Borne Outbreaks of Typhoid

Dr. C. V. Chapin, Providence, R. I.: An outbreak of typhoid fever occurred among the customers of a certain dairy in Providence. The only evidence that the milk supply is the cause of typhoid fever is in the excess of patients among the persons supplied. Out of 600 dealers in Providence, 155 have had one or more cases of typhoid fever during the last four years. In a study of sixteen outbreaks the distribution of the cases in point of time suggested that the infection was not continuous, but depending on a single distribution of the milk. As shown by Davies, Craig, and others, carriers cause infection only in an irregular and intermittent manner. The occurrence of two or three cases in a route of from 100 to 1,000 families within a week requires careful investigation. When the milk supply is found to be defective, and the source not determined, it should be shut off or Pasteurized, and when typhoid is found among those who handle the milk the patient should be removed from all contact with it. Precautionary measures should be carried out for three or four months from the beginning of the last case.

Campaign Against Yellow Fever on the Isthmus of Tehuantepec

Dr. Francisco Valenzuela, Mexico City: The importance of the international traffic across the Isthmus of Panama has brought to that territory a number of nonimmunes, which has led to a great increase in the number of victims. The campaign according to the doctrines of Finlay was organized under Dr. Garcia at the city of Tehuantepec in May, 1904, and subsequently extended to the whole of the isthmus. The excellent results obtained are a matter of congratulation to all. The passenger traffic is under the charge of sanitary agents on board the cars of the Tehuantepec Railway. When a passenger is found to be ill the agent investigates the case, taking into consideration the sanitary condition of the country from which the sick person comes. A report is forwarded to the sick man's destination as well as given to the agent on the train with which the passenger desires to connect. This traveling agent collects all the news possible, thus enabling the chief of the service to receive daily and timely reports of all cases of an alarming character. Isolation of the sick, destruction of the mosquitos by fumigation and the covering of ponds and swamps with oil to destroy the larvæ are the three principal factors in suppressing yellow fever.

Scope and Value of Lectures

Dr. Herbert D. Pease, New York City: Our form of government places the responsibility of government on the citizens as a whole. Never in our history has the public been more alive to the details of administration than at present. In my opinion, we may say that the cardinal principles in educational work in hygiene are as follows: A simpler statement of the known, the unknown and the debatable. The manner and method of expression must be secondary but they are nevertheless of vital importance for success. The speaker must insist on getting the audience and then he must hold them or he is inefficient. Without money the task is greater, but is by no means hopeless. In the pioneer work against tuberculosis those who have had the least money have made greatest progress because lack of means has necessitated more volunteers. To be assured of an audience one must advertise and continue to advertise by special letters, handbills and multiple letters, and even newspaper advertisements. In advertising the subject of a lecture should at all times receive the greatest emphasis; then follow with the names of the speakers, allowing the time and place to come after this. Every epidemic should be used as an opening gun in the campaign against that particular disease. The larger advertisements should be put out first and later followed with the cards, multiple letters, etc. First should be presented in the lecture the problems already solved, next those not entirely solved, and third topics about which there is controversy. Pictures or lantern slides should be used in effective lectures on certain subjects. These slides may be interspersed with moving picture slides, which adds a certain amount of interest to the program.

(*To be continued*)

UTAH STATE MEDICAL ASSOCIATION

Fifteenth Annual Meeting, held at Ogden, Sept. 21-22, 1909

(Concluded from page 1679)

Mistakes in Tabes Dorsalis

Dr. W. Brown Ewing, Salt Lake City: At the outset I must disclaim any intention of finding fault with the surgeons or the specialists in any line of medicine, but insist that extreme care should be taken in making the initial examination of the patient, so as to avoid errors. This disease occurs between the ages of 30 and 50. The classic symptoms should be well-known and easily lead us to a diagnosis in typical cases, but a number of unusual symptoms occur in some cases. There is liability of confounding the various crises of tabes dorsalis with gastric ulcer, diseases of the throat and rheumatic complaints. Often the early symptoms of the disease are referable to the bladder, such as cystitis. The attention of the surgeon should be called to tabetic joints, which may closely resemble various surgical conditions. I have long had a settled conviction that there is great danger in the overtreatment with mercury in patients giving a syphilitic history, and there is liability of spinal disease following excessive use of this drug, the symptoms of which are mistaken for the symptoms of tabes. A masterful inactivity is often the best treatment. As a rule, it is unwise to operate on tabetic joints, since the trophic changes are such that good results cannot be expected.

DISCUSSION

Dr. P. E. Jones, Salt Lake City: There is scarcely any other disease of the spinal cord whose diagnosis can in most cases be made with such uniform certainty as tabes dorsalis, and yet it is a notable fact that this disease is more frequently mistaken for various local disorders than perhaps any other. I have seen a diagnosis of gastric ulcer, or of appendicitis, made and the patient sent to the operating room with no visceral disease present at all. I have seen patients with painful joints and extremities kept on the salicylates for weeks under the mistaken diagnosis of rheumatism. I have seen patients with irritable bladder and disturbances of micturition treated for a local trouble when the seat of the disease was in the cord. The essential point is to think at once of the possibility of tabes and look for the distinctive objective symptoms, the principal ones being absence of tendon reflexes and immobile pupils. When the full ataxic stage of the disease has been reached, even "he who runs may read." Dr. Ewing calls attention to the possible ill-effects of the long-continued use of mercury. I have been long convinced of the ill effects of this potent but toxic drug.

Dr. Frederick Clift, Provo: I believe that the early symptoms of tabes are often overlooked and that many a patient goes on for years under treatment for some other ailment until the disease is so far advanced that little, if anything, can be done to arrest its progress or mitigate its effects. Mercury has its indications, but I, too, am inclined to think that great harm may result from its prolonged use in this disease.

Dr. A. C. Behle, Salt Lake City: I recall one case of tabes dorsalis in which a diagnosis of gastric ulcer with stenosis was made. The diagnosis was made by a general practitioner but the patient was referred to a prominent surgeon and the diagnosis was accepted without further examination. Gastroenterostomy was performed for the relief of the condition, and a secondary operation for "vicious circle." The patient remained in the hospital for thirteen weeks afterward, but still continued to suffer distress in the region of the stomach and had other gastric symptoms. On seeing the case I was satisfied that the patient was suffering from tabes, but in order to verify my conclusion I sent him to Dr. Ewing for a diagnosis, requesting the man to say nothing regarding the history of the operations he had undergone. Dr. Ewing promptly made a diagnosis of tabes and gave an unfavorable prognosis. While we may recognize the disease as incurable, I think that we should give our attention to cystitis and urethral irritation, for these patients want relief from these distressing symptoms of the disease. The picture of mental dejection we so often see will change to a relatively peaceful state of mind if these troublesome symptoms are given proper attention, for when we ignore these ailments it tends to encourage our patients to seek the advice of charlatans and the various mental healing sects.

Dr. S. L. Richards, Salt Lake City: A man was sent to me from the southern part of the state. While branding cattle he suddenly felt a peculiar sensation in his lower extremities with decided weakness. In a short time he was unable to use his legs. A diagnosis of hemorrhage of the cord was made. I began to get shaky about my diagnosis when I took him to a specialist who expressed the opinion that the patient had all the cardinal symptoms of tabes dorsalis. The patient was sent back home with an unfavorable prognosis. Four months later I learned that he had entirely recovered and is now perfectly well. The sudden mode of onset made me think of hemorrhage of the cord rather than tabes, for the latter comes on gradually, whereas in this case the paralysis developed within ten days from the onset of the symptoms.

Dr. G. Robinson, Provo: I have seen this disease confused with multiple neuritis. Recently a patient came to me with a diagnosis of tabes, but the history of the case showed it to be one of multiple neuritis of alcoholic origin. No examination was made of the reflexes to determine the presence or absence of the reflexes. This should not be overlooked. The Argyll-Robertson pupil is characteristic of tabes. An unfavorable prognosis was given, yet the patient has continued to improve. Wrist-drop and foot-drop, which were present when I first saw the patient, have practically disappeared, and the only symptom present of tabes is absence of the knee-jerk, which is not a symptom of unvarying importance as it may occur in healthy individuals. The disease is often confused with anterior poliomyelitis. We should exhaust every means at our command in making a diagnosis, but we should not rely too much on any one or two symptoms, as we may be misled.

Dr. C. F. Osgood, Ogden: Does Dr. Ewing know of any invariable index for determining the time when mercury should be suspended in any given case? How are we to know when enough has been given and more would work mischief?

Dr. W. Brown Ewing, Salt Lake City: My plea is for more care in the making of the diagnosis. The discussion emphasizes my experience. I never saw a case of wrist-drop in tabes. One may find deformities of the foot and relaxation of the muscles and tendons around the joints, with a tendency to clubfoot, but I never saw a case of true wrist-drop or foot-drop in this disease. I confess that I do not know when to discontinue the use of mercury; that is, I do not always know how far to push the drug. In the treatment of the third stage of syphilis I have used antisyphilitic treatment of the most intense character and pushed it to the limit, but I have never yet gone over eight days in the use of mercury without producing constitutional effects of the drug.

New Observations on Spinal Anesthesia

Dr. A. W. Morton, San Francisco: The technic is that which I have employed since 1900. My experience with spinal anesthesia covers 4,000 cases. I have demonstrated the method that I use in producing spinal anesthesia in all the principal cities in this country, and in many foreign medical centers. Tropococain is prepared in doses of 1 grain each, which is sterilized by exposing it to a temperature of 300° F., dry heat, for fifteen minutes. The sterilized drug is placed in small glass tubes, and closed by fusing the end of the tube. The tube may be closed with a cork dipped into sterilized paraffin. The needle used is of steel wire No. 9 gage, 3½ inches long, with a short bevel, and is so made that it can be readily attached to an ordinary Luer glass syringe. As to the technic, the needle is introduced at a point between the third and fourth lumber spaces, in the median line, and is pressed steadily through the tissues into the spinal canal. The cerebrospinal fluid escapes through the lumen of the needle and flows into the barrel of the syringe. Diminished resistance, after the needle has been inserted the proper distance, indicates that the spinal canal has been reached. The syringe has the dose of tropococain already in it, with the piston closed. The syringe is then attached to the needle and the piston is slowly withdrawn; as this is done, the cerebrospinal fluid will pass into the barrel of the syringe, dissolvign the tropococain in the cerebrospinal fluid, which is immediately returned to the subarachnoid space by pressing the piston in. Within 10 minutes, with the maximum dose of tropococain (1½ grains), analgesia extends all over the body. When it is desired to produce analgesia in the upper part of the body, a syringe of 20 c.c. capacity is used, the required amount of cerebrospinal fluid drawn off into the syringe and, after the solution of the drug is effected, returned to the spinal canal as already described. The tropococain dissolves more quickly if the barrel of the syringe is rotated from side to side but without withdrawing the needle. As a rule, analgesia lasts from an hour and a half to two hours, and is so deep that operations may be undertaken with the satisfaction of knowing that the sense of pain is totally abolished. If for any reason the operation is to be prolonged beyond the usual time, the dose may be repeated according to the technic already described. Tropococain has a local action, passing directly into the nerves at the spinal centers, and it acts on the body as high as it passes into the cerebrospinal fluid. Very little enters the circulation proper and it is practically free from toxic effects. It paralyzes the nerve cells that carry the sensation of pain. It has little disturbing effect on the tactile, heat or motor cells of the body. It is especially indicated in organic disease of the heart, lungs, or kidneys, where a general anesthetic is contraindicated. It prevents shock. Its use is indicated in the aged. There is practically no disturbance of the gastrointestinal tract. It is indicated in operations on the tongue and superior maxilla; in fact, any operation about the buccal cavity where there is danger of pus and blood entering the larynx. It is a satisfactory anesthetic in removal of goiters. In obstetric work it produces complete relaxation of the cervix and perineum, and does not interfere with uterine contractions: for this reason it prevents lacerations and hastens labor, which is painless. The after-effects are not alarming. If the heart's action becomes inhibited under its influence, the administration of the proper dose of adrenalin, or 1/100 of a grain of atropin is indicated. Vomiting occurs in about 3 per cent. of all cases and usually occurs about ten minutes after the injection is made. Headache occurs but is rare. It is relieved by having the patient maintain the reclining position with an ice-cap applied to the head.

Value of Early Diagnosis in the Treatment of Epidemic Cerebrospinal Meningitis

Dr. R. C. Smedley, Salt Lake City: Through the efforts of Flexner the profession has been led to a better understanding of the pathology of this disease; he has placed within our reach a therapeutic measure of unquestionable efficacy. An early and positive diagnosis of this disease should be made by lumbar puncture. If the cerebrospinal fluid withdrawn is cloudy, give the first full dose of serum at once without waiting for the bacterial examination, although further doses are only to be given if the *Diplococcus intercellularis* is found in the cerebrospinal fluid. The serum is of no value in other types of meningitis. At every dose give as much as possible—the amount given, however, should equal the amount of cerebrospinal fluid withdrawn. Repeat the dose every twenty-four hours or at shorter intervals; repeat daily till four full doses have been given. In all cases, if diplococci persist after four full doses, continue injections until they disappear. After that the treatment depends on the requirements of the case. A medium-sized aspirating needle is introduced into the spinal canal between the third and fourth lumbar vertebræ. If the fluid withdrawn is clear, it does not necessarily rule out the existence of epidemic cerebrospinal meningitis. The addition of one-third alcohol (95 per cent.) will cause marked turbidity if meningitis is present. If the fluid is turbid place it on ice for a short time to favor clot formation or centrifuge and examine with a microscope. The cover-glass preparation is stained with aqueous saturated solution of methylene blue. If more than one lymphocyte or polynuclear leucocyte is found in the field it indicates leucocytosis, which points to the probability of cerebrospinal meningitis. In the early stage of the disease the *Diplococcus intercellularis* is found in varying numbers, mainly free; after the first injection of the serum these micro-organisms partially disappear, and after subsequent injections tend to disappear entirely. The serum must be brought into direct contact with the spinal fluid. It is of practically no value given subcutaneously. Improvement occurs as a rule after the first injection. The temperature falls and some cases show a tendency to terminate by crisis. The mind clears up, but rigidity of the spine persists for some time. Flexner's serum reduces the mortality of this disease to a figure somewhere between 10 and 25 per cent., as compared with from 57 to 91 per cent. without the serum.

DISCUSSION

Dr. W. R. Tyndale, Salt Lake City: The value of an early diagnosis must be apparent to every one. We should always have the symptoms of this disease in mind, since sporadic cases are easily overlooked when epidemics do not exist. The early symptoms of all acute, infectious diseases are very much the same, but high fever, vomiting and retraction of the head should make us be on the alert, for if the serum treatment of this disease may be relied on to accomplish anything it should be administered early in the disease and before serious destructive changes have taken place.

Dr. W. R. Calderwood, Salt Lake City: I believe that the mortality of this disease can be materially reduced by the early and intelligent use of this serum. Too much stress cannot be laid on making an early diagnosis. Flexner's serum seems to be the remedy that promises the best results.

Dr. Ralph T. Richards, Salt Lake City: Dr. Smedley suggests that the needle employed for aspirating the suspected cerebrospinal fluid be introduced between the third and fourth lumbar vertebræ. You will often fail to obtain the fluid in this location, but if the needle is inserted between the second and third lumbar vertebræ, you will seldom fail to find it.

Dr. J. T. Sharp, Salt Lake City: In 1906, I saw many cases of this disease and came to the conclusion that the mortality of epidemic cerebrospinal meningitis is very high. In some cases the early symptoms are difficult to recognize; in some the nervous symptoms are of the most violent character. The point I desire to make is this: I was struck by the pathologic picture disclosed by the autopsy. I had the privilege of doing several of these autopsies, and as I took the skull-cap off I was impressed with the utter helplessness of trying to combat a disease so destructive in its consequences—pus, blood and leucocytes were everywhere, the membranes were congested, adherent and oozing with pus. If Flexner's serum is really curative, and I have no doubt it is, it should rank as one of the great discoveries, and if there is just one horse that is generating this serum, my earnest hope is that he will not die.

Dr. Philo E. Jones, Salt Lake City: Does Dr. Smedley know of any ill effects that are likely to follow the repeated introduction of the needle into the spinal canal? I have read that these subdural injections are not wholly devoid of danger.

Dr. R. C. Smedley: The best place to introduce the needle into the spinal canal is a matter of choice. I am sure that the fluid can be obtained at a point between the third and fourth lumbar vertebræ. Some prefer the second interspace. In view of the grave pathologic lesions found beneath the skull-cap, it is important that the serum be brought into direct contact with the subdural injection. I have not had my attention drawn to any ill effects following the injection of the serum, even when these injections are repeated. But I believe that cases have been reported of sudden collapse following these spinal injections. While in Boston I saw several patients who were treated as long as six weeks with the serum, daily injections being made or on alternate days, and with no bad results. Now and then medical literature reports a fatality following the use of the serum. Possibly the position of the patient may have something to do with such accidents. I believe that faulty technic may throw suspicion on some remedial measures that are otherwise safe and efficient.

Degenerative Changes in the Spinal Cord in Pernicious Anemia

Dr. J. R. Morrell, Ogden: Lack of uniformity in the symptoms of pernicious anemia suggests an underlying infecting agent, having a marked hemolytic power whose toxins cause the gastric and intestinal disturbances and degenerative changes in the cardiac musculature and in the central nervous system. The pathologic changes in the spinal cord bear no direct proportional value to the intensity of the clinical symptoms. In well-marked cases the degenerated areas of the cord can be seen with the naked eye, appearing as darker areas in the white substance of the cord. In the seven cases studied and made the subject of this report, the regions of the cord involved were not constant, but varied considerably. In five out of six cases of pernicious anemia, pathologic changes in the cord were demonstrable, and in four of these they were quite extensive. The structural changes were most marked in the cervical region. In two cases there was considerable ataxia during life, and in one, associated for a time with marked spasticity. All cases showed at some time more or less nervous involvement.

DISCUSSION

Dr. W. Brown Ewing, Salt Lake City: In the description of the pathologic findings of the cord in pernicious anemia there seems to be a striking similarity to those found present in syringomyelia. The regions of the cord involved, as illustrated by Dr. Morrell, are certainly much like the findings in syringomyelia, and some of the symptoms are likewise very similar. The involvement of the cord is considerably more extensive than I had supposed a post-mortem examination would disclose.

Dr. J. R. Morrell: I did not mention that changes in the cord may occur independently of pernicious anemia. What we have grown to regard as typical lesions may exist without any appreciable changes in the blood.

Puerperal Fever

Dr. E. I. Rich, Ogden: Puerperal fever is an infection carried to the parturient woman by an infected agent. It is generally a mixed infection. The streptococcus is most frequently found and is present in nearly all serious and fatal cases. The gonococcus comes next. The staphylococcus and colon bacillus and a number of putrefactive anaerobic bacilli are frequently found, and in rare cases the Klebs-Loeffler bacillus and the pneumococcus. The recently emptied uterus presents a particularly favorable field for the invasion and growth of micro-organisms. As to the sources of infection, bacteria must either be present in the passages to the uterus or must be introduced from without. The gonococcus is the only pyogenic organism that can live and thrive in the normal vaginal secretion of a pregnant woman. The infecting organism invades the walls of the uterus along the lymphatics or veins and is thus conveyed to neighboring tissues and organs. In making a diagnosis, too many jump at the conclusion that fever following childbirth means infection. The entire body should be carefully examined and a diagnosis arrived at by a process of exclusion, after first thoroughly unloading the bowels. In the last 300 deliveries I have not once used a douche because of fever, and in only four or five cases in which lacerations were present. Of course, if the uterus is filled with infected blood clots or putrid material, after careful cleaning out is done with the hand or a large, dull curette, there is no valid objection to irrigation. In puerperal septicemia the uterus must be cleared of all necrotic and putrefactive material without disturbing the underlying protective wall of leucocytes. In virulent streptococcus cases Nature does not have time to form a protective wall of leucocytes. In these cases we must rely chiefly on constitutional treatment, as the poison is beyond our reach. One thorough irrigation with hot normal salt solution (3 gallons), followed by at least ½ gallon of 50 per cent. alcohol and sterile hot water, with one teaspoonful of iodin to a quart of this solution may be employed. Hysterectomy in acute puerperal sepsis is now generally condemned.

Nose and Throat Conditions of Interest to the General Practitioner

Dr. R. R. Hampton, Salt Lake City: The location of the tonsil is such that bacteria entering the oronasal cavity, from the day of birth, are directed toward the tonsillar crypts, which act as receptacles or culture tubes in which bacteria of every variety, entering the fauces, may be cultivated. The mucus in the crypts serves as a culture medium. The glands which furnish this mucus are located just outside the tonsillar structure. These peritonsillar mucous glands are most numerous at the base of the tonsil near the bottom of the crypts, which explains how tonsillar abscesses at times follow tonsillitis. Bacteria multiplying in the crypts, elaborate vaccines which are taken into the tonsil by the lymph currents, and thus entering the system they are absorbed. These toxins cause the tissue cells to generate opsonins which prepare the pyogenic bacteria for phagocytosis. The salivary corpuscles now seize the bacteria, and together they are pressed out into the oral cavity in the act of swallowing. In swallowing, the superior constrictor muscles compress the peritonsillar glands and force the mucus into the crypts, and this same force or pressure forces the contents of the crypts into the orval cavity. The tonsil, with its crypts, makes it possible for the system gradually to absorb the vaccines from the crypts, and thus produce immunity without systemic toxemia. The tonsil is most needed during the first three years of life; it probably functionates until puberty or later. Tonsillar disease is often insidious and goes unrecognized until the damage to the neighboring organs, and often to the general health of the patient, is almost irreparable. The diseased tonsil is more or less hypertrophied in all parts, and while not obstructive as a rule, they are sometimes very large, extending upward and backward often as far as the Eustachian tube on which they may press, interfering with the air passage and blood circulation of the ear and causing disturbances of function. The drainage of these diseased tonsils is extremely faulty, and the result is that pent up secretions become foul smelling and exceedingly irritating. Whatever the function of the tonsil is we do not know, but we do know that a diseased tonsil is a menace to the general health. Health is impaired by direct infection. Tuberculous glands of the neck and often pulmonary tuberculosis may be traced directly to diseased faucial tonsils. Instead of injury to the voice, the only effect of removal of the tonsils is a decided improvement in the voice. Middle ear deafness may have its origin in at least three ways: from the extension to the tympanum of inflammatory conditions in the adjacent tissues of the Eustachian tube or pharynx; to alterations in the vascular supply in that cavity; to the interference with proper and adequate ventilation of the tympanum from the Eustachian tube. Middle-ear disease may be caused by bacteria that gain entrance through the tonsils, which argues that the tonsil should be examined in middle-ear trouble. The tonsillar mass may interfere with the function of the Eustachian tube. In normal conditions this tube is patent, but not open. In deafness look for diseased tonsils and operate when they are found. Postnasal obstructions should be removed before orthodontia is attempted.

Necessity for Early Treatment of Strabismus

Dr. Fred Stauffer, Salt Lake City: It is only by early treatment that we can hope for cure in strabismus, and by cure is meant the restoration of binocular single vision. The principles involved in this paper deal chiefly with the comitant squint and do not apply to paralytic strabismus. To understand the causes of squint and its treatment it is imperative to understand the physiology and refraction of the normal eye. Donders, in his researches for the cause of squint, found that a large majority of patients with non-paralytic comitant convergent squint were hypermetropic. The squinting eye is often astigmatic, or has other defects that interfere with a clear image. While the majority of convergent squints are hypermetropic, there are many hypermetropic persons who exercise perfect binocular single vision. It remained for Claude Worth of London to fill the breach through his researches and critical study of over 2,000 cases of squint. He discovered the fusion sense of which there are several degrees of development. Convergent squints appear early in life—at the age when the child begins to pay close attention to surrounding objects, usually between the ages of one and three years. The object of treatment is to restore parallelism of the visual axes and restore binocular single vision. If one eye is permitted to squint for a considerable time it becomes amblyopic from disuse. In some cases the squint eye is congenitally amblyopic. If treatment is not commenced before the fifth or sixth year there is little hope of restoration of binocular vision. The rational thing to do is to paralyze accommodation temporarily with atropin, and after measuring the refractive error with the retinoscope, prescribe a lens for constant wear that will make the eye emmetropic. Thirty per cent. of convergent squints treated early by this method are curable. If this fails there is generally insufficient development of the fusion sense. The fusion sense can be trained by the use of some form of stereoscope, such as Worth's amblyoscope. A child who is old enough to develop a squint is old enough to wear correcting glasses. Early treatment cannot be too strongly urged, because it eliminates the necessity for operative interference, and because if treatment is long delayed it becomes impossible to restore binocular vision. Non-paralytic divergent squint comes on later in life and generally requires operation. When fusion training and correcting lenses fail, operative treatment is indicated. The age of 5 years is late enough for operative treatment, which allows ample time for other treatments. The point I desire to emphasize is the necessity for commencing treatment as soon as the child begins to squint.

Diagnostic and Therapeutic Value of the Roentgen Ray

Dr. C. F. Osgood, Ogden: Radiology to-day occupies a prominent place in medicine and surgery. The *x*-ray is not a panacea for all ailments, but is limited in its use. For diagnostic purposes it is often indispensable, especially in determining the existence of obscure fractures or dislocations, many of which are diagnosed as sprain. The use of the *x*-ray prevents such blunders. In the diagnosis of pleural effusions and enlargement of the heart, the fluoroscope gives valuable confirmatory evidence, as the exudate is quite resistant to the ray. The line of demarcation is more marked in purulent than in serous exudates. In the treatment of pathologic conditions it is an agent of proved efficiency. Of the diseases most successfully treated by the *x*-ray, mention may be made of epithelioma, lupus, chronic eczema, tuberculous adenitis, exophthalmic goiter, and leucemia. I have successfully treated with the ray three cases of epithelioma with no recurrences, two of chronic eczema, one very old case of lupus and one of leucemia. In lupus it is preferable to the Finsen light.

Etiology of Phlegmasia Alba Dolens

Dr. Eugene H. Smith, Ogden: This is a condition dependant on various causes and occurring as a complication or sequel to different diseases. It often indefinitely prolongs an otherwise rapid convalescence. It occurs most frequently following disturbances of circulation in the pelvis, but it also follows operative procedures in the upper abdomen. It occurs as a complication or sequel to appendicitis, yet it may develop when no operation has been undertaken. As to the frequency of its occurrence during the puerperium, statistics vary from 12 to 10,000, to 23 to 6,000. Operative intervention or other obstetrical procedures seem to play no part in its production, as it follows as frequently the clean case as the case in which trauma and infection were probable factors. Thrombosis not infrequently occurs in typhoid fever, pneumonia, tuberculosis and influenza. In its production in these conditions, debility, recumbency and infection must play a part. When the veins of the lower extremities are involved the left side is most frequently the seat of affection. Of predisposing causes, the anatomic arrangement of the iliac and femoral vessels seems to favor its occurrence. The left iliac vein is subject to pressure from distention of the sigmoid or rectum, thus favoring thrombosis of the left side by retarding the blood stream.

The venous stasis and dilated condition of the vessels in varicose veins is a local and predisposing cause, favoring the development of phlebitis and thrombosis. In other words, mechanical interference is a local predisposing factor. Hemorrhoids like varicose veins, with the added element of possible infection, share in the production of circulatory disturbances. Pathologic states of the interior of blood vessels cause the formation of thrombi, as endocardial inflammations, and lead to emboli, favoring the development of thrombosis. Of systemic conditions increased coagulability of the blood is a factor in the production of thrombosis. This is likely to occur during the puerperium because of the process of involution and the loss of blood, not to mention the normal increase of the fibrin elements in the blood which occurs in pregnancy. It would seem that the probabilities are strongly in favor of the non-infectious nature of operative cases. It is probable that a combination of several factors may bring about its occurrence without the participation of microorganisms. Trauma is probably the most active factor in the production of many cases.

MINNESOTA STATE MEDICAL ASSOCIATION

Forty-first Annual Meeting, held at Winona, Oct. 12-14, 1909

The President, Dr. Cornelius Williams, in the Chair

The officers elected were given in The Journal, Oct. 30, 1909, p. 1493.

President's Address: The Physician's Place in the Community

Dr. Cornelius Williams, St. Paul: The proper position of the medical man in the community is not fully appreciated, either by the physician himself or by the lay citizen. Long years of communal isolation have bred ideas that have become convictions on the part of the public. The physician is stamped, as it were, with a kind of bar sinister. By common consent, the doctor is relegated to the doing of certain prescribed duties and the bearing of certain burdens demanded and required because of the bar sinister—and gratis. The physician, because he is a physician, is required to give freely of his time and skill whenever and wherever needed without hint of compensation. As well would it be to require of the artisan that he should build hospitals, and the dealer that he should completely furnish them, as that a physician should give gratis of his time and labor and skill by which and through which alone their conduct is possible. My proposition is that the bar sinister should be broken, that the physician should receive full and usual compensation for his work, in fact, that he should come into his own. How shall this be brought about? It cannot be done by "educating the public," because one cannot educate a class by mere reasoning and argument to do a thing contrary to established custom. I mean that all gratuitous service on the part of the physician to the public shall cease. There is properly no mystery about medicine as a science or an art, and there is no reason why the whole people should not acquire a knowledge of the fundamental truths that underlie medicine as a science and of its practice as an art, and an understanding of such art and science will make the human animal physically and intellectually superior.

This elevation of the race must come through medicine, and this is the mission of the medical profession. There are very divergent views, as to where the initial work must fall. I declare that it is only by a participation in politics that the physician may accomplish his whole mission, and that such participation is one of his highest duties. From the very nature of his position his duties place him in the rôle of police; he must suppress or regulate whatever is injurious to the peace, health, morality, general intelligence and thrift of the community and its internal safety. Isolated in the sense that there is no concert of action, the medical man is a negligible quantity, as to any influence, either for good or bad legislation, but, united into a guild of workers, the medical body would be a great power to determine the outcome of an election and to direct the measures of government.

I then propose the formation of a medical guild to comprehend every medical man in the state. The object shall be to become the highest political power in the highest sense of the word. In my opinion, the foundation of a medical guild, together with another insurance guild, would be an ideal method for the closer alliance of the medical profession for mutual protection against an enemy in any form.

In most instances in our state the judiciary is of the highest order, but there are certain rules of practice that are obsolete and injurious, particularly as pertaining to the trial of cases involving the practice of medicine and surgery. Even the judicial mind may seem to be warped by what is technically known as passion and prejudice. The medical guild would seem to be the only effective way of eliminating men of such minds and methods.

The medical guild then, if I may be permitted the expression, might be called a communal deobstruent, whose office would be to purge society of some of its evils, and to modify some of the evils of intestinal malassimilation of the body politic, to raise the opsonic index of that body, and to afford the proper and measured antitoxin required to correct a morbid condition induced by insanitary ways of living. I would expect that the propositions contained in this paper will meet the treatment usually accorded to the pioneer who breaks out of the beaten path, but I am convinced that the things suggested are practical of doing, and that their doing would be of exceeding benefit to the community, and would inaugurate a new era in medicine.

SYMPOSIUM: EPIDEMIC ANTERIOR POLIOMYELITIS

Previous Epidemics of Anterior Poliomyelitis

Dr. Haldor Sneve, St. Paul: Over fifty epidemics of this disease have been recorded. Medin, of Stockholm, gave the first account. Later his pupil, Wickman, also of Stockholm, made the most careful study ever made of any epidemic disease, and showed that the disease is an acute infection, contagious, and may assume clinically one of numerous forms of disease heretofore regarded as distinct, such as the cerebral infantile palsy (of Strümpell), the ophthalmoplegia of Wernicke, the bulbar palsy of Duchenne, Landry's paralysis, transverse myelitis, and abortive forms. Giersvold, of Norway, has given us the same facts. We needed the masterly pathologico-anatomic studies of Harbitz and Scheel, of Norway, to give a correct insight of the nature of the disease process. They showed it to be a specific leptomeningitis, the virus starting from the pia as a base, following the blood-vessels into the whole of the cerebrospinal tract, destroying or temporarily affecting the ganglion cells, especially where the blood supply is the most rich. Geirsvold gave the only positive evidence of the nature of the virus. He found a diplococcus in the spinal fluid in twelve cases, and inoculated animals with the germ, producing paralysis and death. For the present we must accept the diplococcus described by him as the active causative agent. Entry is probably through the nose and throat.

Four-fifths of the cases occur in children under 6 years of age, the proportion of males to females being 3 to 2. Epidemics seem to follow rivers and appear mainly in the months of July, August and September. The period of incubation is from one to five days. The onset is usually sudden with meningeal symptoms, and fever in the neighborhood of 101 F. Healthy children are as liable to be attacked as the weak. The mortality is about 10 per cent. in children and 25 per cent. in adults. About four-fifths of the patients have paralysis, and 25 per cent. of these completely recover; 75 per cent. of the remainder recover partially. Abortive cases present the greatest difficulty in diagnosis as they may appear to be cases of influenza, meningitis or of polyneuritis, and we can only suspect them when occurring in the presence of an epidemic. A study in the Rockefeller Institute seems to indicate that diagnosis of this disease by a serum reaction is impossible. Lumbar puncture may reveal the Geirsvold microbe besides being a valuable therapeutic measure.

The first thing in treatment is rest; hexamethylenamin may be given in the acute stage. Antiseptic gargles and nose washes may have prophylactic value; 1/10 grain of calomel every hour, with salicylates, may be given when indicated. Dry cupping or ice bags or counter irritation may be used over the spine. The paralyzed limbs should be supported; later strychnin may be given; in about two weeks massage, vibrations, electricity, and elastic bands or orthopedic appliances should be employed. This is not a new disease, but is even mentioned in the Bible. That Mephibosheth became lame was ascribed to carelessness of the nurse in letting him fall. Sporadic cases are with us always and occasionally an exacerbation occurs which we call epidemics.

Minnesota Outbreaks of Anterior Poliomyelitis in 1908

Dr. A. S. Hamilton, Minneapolis: Three epidemics of anterior poliomyelitis, all more or less extensive, appeared in Minnesota in 1908. At Hibbing, 16 cases were reported; at Northfield, 30; and at Barnum and Moose Lake, 45 cases. In addition there were numerous isolated cases of the disease scattered widely through the state, and in a few localities, in addition to the above, the number of cases was sufficient to constitute a limited epidemic. All epidemics came in the autumn and the cases disappeared after the onset of cold weather. Together there were probably 150 or more cases in the state; 13 deaths were reported to the State Board of Health as due to poliomyelitis. Clinically the cases were much the same as have been observed this year and also in preceding epidemics. At Barnum, however, the number of instances where more than one case occurred in the same family was very much greater than usually reported.

Discussion on Poliomyelitis

Dr. Donald B. Pritchard, Winona: Anterior poliomyelitis was epidemic in Winona during the past season, the first case occurring in June and the last in August. The cases were reported to Dr. Bracken who sent down Dr. Hill, and instead of 6 or 7 it was found that there were about 25 cases. Dr. Hill went into the history thoroughly and found the cases occurred in the dry and dusty season. The distribution was over a distance 2½ miles long by 1¼ miles wide. There seemed to be no connection between the cases; families in which there were from 6 to 10 young children having only one case. In one family with 2 children both had it. The cases seemed to occur in the part of the city that was not sprinkled, and we even found cases where only one side of the street was sprinkled on the unsprinkled side. It was remarkable to see how that basis held out. In view of this fact we had the streets sprinkled, beginning on the fifth of the month and on the twelfth we had the last case.

Dr. E. D. Keyes, Winona: I saw about 6 cases during July, and one patient who came in about a month ago from the country. This last was a case of ascending paralysis in a girl 17 years old. The cases with one exception were isolated cases, the exception being in a family of 12 children in which 2 had the disease. The cases were scattered over the whole city and there seemed to be no connection between one case and another. It was an epidemic condition rather than contagious disease. The general behavior of the disease seemed to indicate that dust played some part in carrying the infection.

Dr. F. W. Bullen, Hibbing: During the summer of 1908 there were 15 cases of acute anterior poliomyelitis in Hibbing and vicinity, the first 2 cases occurring June 15 and July 4, and the balance during the last week in July and the first week in August. The weather was dry and dusty. In only 2 instances did 2 cases occur in the same family. Ten of the families traded at one grocery store and 2 children of members of the firm had the disease. One case was that of a young man of 24, one boy of 6, the other patients being 1 and 3 years of age; 5 were females and 10 males. The initial symptoms were those of acute gastroenteritis. Vomiting was an early symptom and diarrhea was present in nearly all cases. Temperature ranged from 101 to 104 F., continuing from 3 to 6 days. Sore throat occurred only once. Kernig's sign was present only once. Paralysis appeared on the third to the seventh day, of the flaccid type, and the paralyzed extremity was usually painful on motion only. There was only one fatal case, death being due to paralysis of respiration. No autopsy was permitted. This was thought to be a case of acute polioencephalitis complicating a poliomyelitis, but may have been an infantile hemiplegia. Another patient showed convergent strabismus on the fifth day with no other paralysis. This patient completely recovered in 9 months. The case of the young man of 24 somewhat resembled Landry's paralysis. He also had urinary retention for several days. The rest of the cases were of the ordinary spinal type; 2 were of the abortive type with complete recovery in less than 3 months. Of the 15 patients one died, 6 have completely recovered, one has been lost sight of, and 7 still show more or less atrophy and paralysis. There has been only one case this summer, a boy of 2½ years, with paralysis of the lower extremity only.

Dr. H. W. Hill, Minneapolis (Minnesota State Board of Health): There were at least 150 cases of anterior poliomyelitis in the state last year. The distribution of the cases was very wide. The number given represents perhaps only one-fourth of all the cases, since many cases were not recognized and many were not reported. We do not know how many cases we had, but those of the abortive type were legion. This year the cases were much better reported. I was in one locality where fifty cases had been reported, and I was able to satisfy myself that one out of four was probably poliomyelitis. An interesting feature is the two types of disease. One which we call the Scandinavian type is accompanied by sore throat, but in the type we have here in Minnesota the sore throat is not present. In regard to nationality, in Winona we found that a great many Poles had the disease, while in other localities we found the prevalent type existing in families living under insanitary conditions and with poor nutrition. We have not been able to find any evidence that the disease is infectious or contagious. While a few older people were attacked, it may safely be said that the disease is confined to children. In studying it epidemically we have gone into everything we could think of. We went into the question of eating dirt, and of eating vegetables raw out of the garden. We could not find through the state entomologist that any particular insect was more prevalent than in former years; we found weeds very abundant, but in following up that lead it came to a blind end. We were unable to find anything in that way except the dust. We found in all cases where the dust had been the greatest it was of the character that carried horse manure. Another interesting feature is that Dr. C. S. Shore, of Lake City, a veterinary surgeon, reports a disease among colts and young horses almost identical with anterior poliomyelitis.

Dr. H. E. Robertson, University of Minnesota: I performed three autopsies this fall on undoubted cases of poliomyelitis:

Case 1 was that of a boy 2½ years old. He was ill 8 days. After the usual febrile disturbance there was paralysis of both arms and legs, on the right side first, and finally of the bulbar centers. Autopsy was limited to spinal cord. On opening the dura, marked excess of clear cerebrospinal fluid escaped. On section of cord, in upper portion of cervical enlargement was a pin-head-sized hemorrhagic area located in the right anterior horn of the gray matter. The area was soft and bulged on gentle pressure. It extended up and down the cord for a distance of about 5 mm. Cultures from the cerebrospinal fluid showed the presence of a Gram-positive diplococcus, non-pathogenic to guinea-pigs or rabbits.

Case 2 was that of a boy of 9, ill about 60 hours. Complete autopsy was performed and examination of organs was negative except for swelling of lymphoid tissue noted in spleen, lymph nodes, thymus and follicles of intestines. Brain and cord surfaces were deeply congested and clear cerebrospinal fluid was present in excess. Transverse section of cord showed small hemorrhagic foci in the gray matter of the anterior horns, the highest in the right side of the medulla, varying in location from side to side as far down as lower thoracic portion. Cultures from the cerebrospinal fluid gave a Gram-positive diplococcus.

Case 3 was that of a girl aged 3, ill 14 days with paralysis of arms and legs and death from respiratory failure. Aside from congestion and softening of spleen and congestion of pia-arachnoid, the gross lesions were confined to the pons and cord. Hemorrhages were present in the anterior horns as far up as the peduncles of the cerebrum. Only the lower thoracic cord was free from hemorrhages. Cultures from this case were made by Dr. Chesley of the State Board of Health. A

Gram-positive diplococcus was obtained from spleen, heart's blood, lateral ventricle of the brain, cerebrospinal fluid, throat and middle ear. This organism resembles in morphology and cultural characters the coccus described by Giersvold and also by Fox.

Microscopically the lesions in every case have resembled each other: (1) Congestion of vessels, especially those leading to anterior horns. (2) Perivascular infiltration of polymorphonuclear and mononuclear cells, the latter being both lymphoid and endothelioid in type. (3) Infiltration of pia and nerves running from anterior horns. (4) Necrosis of gray matter of anterior horns, especially the ganglion cells, with diffuse infiltration of polymorphonuclear and mononuclear cells. (5) Hemorrhages into gray matter of anterior horns. (6) Thrombosis of vessels in region of hemorrhages (seen only in Case 3). (7) Dilated lymph channels. (8) Occasional infiltration along lines of vessels extending into base of brain and also posterior horns of cord.

Dr. A. J. Chesley, Minneapolis: The Minnesota State Board of Health laboratory has received for examination specimens from 24 cases of poliomyelitis. Spinal fluids were sent in from 16 cases, but 5 showing no growth and 4 being badly contaminated, only 7 were suitable for investigation. From 6 a Gram-positive diplococcus, corresponding in every detail to the description of Giersvold's diplococcus given by Fox, was obtained in pure culture and further experimentation is now in progress. Hearty cooperation of physicians is urged in obtaining nose and throat cultures, spinal fluid, blood, etc., for examination from every case, and in securing permission for post-mortem examinations to be done by competent pathologists as soon after death as possible, that every facility may be had in the effort to determine the cause of this disease, and a specific remedy for its treatment or prevention.

Dr. W. A. Jones, Minneapolis: Eight years ago I saw about 12 cases of general paralysis which agreed closely with the epidemic of the present time. I called them simple neuritis. I believe, as has been suggested, that we are laboring under a misnomer in designating all these cases as anterior poliomyelitis, but, on the other hand, I do not agree with the suggestion that we ought to call everything of this nature anterior poliomyelitis.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Eighteenth Annual Meeting, held in Washington, D. C., Oct. 5-8, 1909
(Continued from page 1683)

The Venereal Peril

Lieut.-Col. Henry I. Raymond, U. S. A., based his paper on "The Eradication of Specific Urethritis from the Army by means of the 'K' package. Reenforced by Military Law and Discipline," on the following postulates:

Specific urethritis is the cause of more non-effectiveness in the army than any other one disease, the venereal diseases alone being responsible for a non-effectiveness equal to the loss of the services of an entire regiment for every day in the year, as shown by Col. John V. R. Hoff, U. S. Army, in his paper on "The Venereal Peril" (read by title).

Soldiers will expose themselves to venereal infection as long as human nature remains unsanctified. Moral suasion alone is inadequate to effect the desired revolution.

To effect escape from the physical ills of a sinful practice is a legitimate end of sanitary endeavor. It is not encouraging vice. The young man who avoids promiscuous intercourse from principle will not be misled through proffered immunity from infection.

A rational method of prophylaxis or prevention of specific urethritis has been devised, its general adoption in the army requiring the enactment and enforcement of a new military regulation making the contraction of gonorrhea a military offense.

There were issued to 576 individual enlisted men out of a garrison of 1,800 who applied for them at Fort Sam Houston, Texas, "K" packages. Of this 576, all of whom supposedly exposed themselves to the possibility of infection, in no case in which the remedy was intelligently applied, did it fail in efficacy. That portion of the garrison which did not make use of the package presented 66 cases of gonorrhea.

Those who did not use the "K" package and who contracted gonorrhea were wilful and neglectful, those who used the package and contracted gonorrhea were indifferent and careless; both classes were proper subjects for military discipline.

When there was no rational method of preventing the disease the contracting of gonorrhea was properly considered not a military offense, but now it may be viewed from a different standpoint.

So strong is the evidence that the "K" package, intelligently applied, will prevent infection, that no exemption should be made, but the unfortunate victim who may claim to have made use of the preventive should be held to have been negligent in its application if not untruthful in his allegation.

Weekly inspections should be made for venereal disease, and any attempt at concealment should be regarded as an aggravating circumstance before the summary court.

The weakest link in the chain of prevention of venereal disease in the army is the lack of a feeling of personal accountability on the part of the enlisted man, fostered by a sense of security from punishment for physical disablement through his own misconduct or through his indifference to rational preventive measures intended to secure his immunity from the ill consequences of his immoral acts.

Disease and Battle Casualty

Major Louis Livingston Seaman, U. S. V., stated that in most of the great wars of history three-fourths of the mortality has resulted from disease and only one-fourth from battle casualty. Most of this loss is preventable and constitutes a crime against humanity and patriotism. Service in six campaigns has convinced Major Seaman of the utter inadequacy of the medical departments of nations, with one notable exception. When it is remembered that this department combats the enemy that kills 80 out of every 100 that die in war, and that all the other machinery of the army kills but 20 per cent., and also that the medical department with its small numbers and limited authority, has to fight the invalidism that sometimes renders an army ineffective before the enemy, one is forced to the conclusion that the situation demands medical reform.

In order to focus the attention of military sanitarians on this subject, Major Seaman has offered a prize of $500, open to the world, in any language, for the best essay on the following subject: "What Should Be the Organization and Status of the Medical Department of Any Army, in Order that its Sanitary and Hygienic Conditions May be Maintained at their Highest Efficiency, so that in the Emergency of Battle, its Units May Best Respond to the Call of its Commanders?" The award of this prize will be made by the Executive Committee of the Seventeenth International Medical Congress, which meets in London, in 1912.

Care of Wounded in Ships

Medical Inspector Bunzo Tomatsuri, Imperial Japanese Army, believed that all surgical interference should be aseptic. Space should be provided in ships of war for original surgery, with possibility of uninterrupted communication by means of elevators and ladders. The greatest care should be taken of the wounded after first aid has been rendered. The provision for transportation and subsistence of the wounded still leaves much to be desired. He recommended the use of sandbag splints for immobilization.

Organization of Naval Medical Department

Medical Inspector Lloyd W. Curtis, U. S. N., discussed the organization of the medical department and the sanitary service of the fleet under present conditions, and described the organization which in his opinion would best meet the requirements of the fleet in view of further expansion, and render the most efficient service both in peace and war. He gave an outline of the duties of medical officers, the medical personnel of the fleet and their duties, the relations of the medical department to line officers. The office of fleet surgeon at present answers no particular purpose.

Best Training for Medical Officers

Surgeon Charles F. Stokes, U. S. N., who considered the question of what should constitute the best training for medical officers, the hospital corps and the ambulance parties of the fleet for sanitary service and as aid to the wounded in time of peace and war, insisted on previous service in civil hospitals and a rigid and exacting examination. He finally believed in the unification of action through the medium of postgraduate instruction in the Naval Medical School. The keynote of instruction in the school should be the cultivation of the senses, and independence of the laboratory and the *x*-ray. The association of naval medical officers with civil practitioners is inspiring. The hospital corps should be intelligent men. The advent of female nurses has made a great change and a signal advance in naval hospital conditions. Medical officers should instruct line officers in first aid work, and the line officers in their turn should instruct the men.

Medical Director John C. Wise, U. S. N., believed in the value of the great metropolitan schools for medical study. Deficiency in preliminary education is the greatest evil in the medical profession to-day. He deprecated the amount of time spent in the laboratory, as graver questions than those of bacteriology are not given so much attention as they deserve.

Medical Inspector Henry G. Beyer, U. S. N., gave his opinions as to the best training for medical officers intended for the positions of fleet and squadron surgeons, and of the principles which should determine their selection for the postion, and also took up the duties and responsibilities of fleet and squadron in relation to fleet sanitary efficiency.

Medical Department of Ship in Action

Medical Director John C. Wise, U. S. N., detailed the most important constituents in principle, and practice of the efficient organization of the medical department of a ship during action, including provisions for, and methods of, rendering first aid to the wounded, and described a scheme for uniform instruction in first aid to sick and wounded. There is a vast difference between the service to the wounded at sea and on land. At sea the horizontal planes are different, the means of communication between levels or decks are vertical, and in addition, every inch of space on a ship is on the firing line. The Geneva flag protects only the hospital ships. The ship's company should be instructed in first-aid methods. The medical department during action should be stationed at sheltered points, and the hospital corps men at places where they can be most useful. Dressings should be provided in plentiful store, freely distributed and never kept en màsse. The transportation should be governed by circumstances.

Hospital Ships

Surgeon George Pickrell, U. S. N., to whom was assigned the topic of the precise functions of the hospital ship and its relation to the fleet in peace and war, urged the necessity of hospital ships in time of peace. He recalled one instance when 22 patients on one battleship needed transfer. A floating hospital should be attached to each squadron.

Surgeon Charles F. Stokes, U. S. N., considered the factors that make the hospital ship an aid to the efficiency of the fleet; emphasized the importance of one in the selection of the personnel, the type of ship and its equipment; the necessity for an extensive disinfecting plant; the imperative necessity of isolation wards; the early recognition of tuberculosis and the importance to the welfare of the fleet, of proper provisions for prolonged treatment of the disease; and the necessity for extensive laboratory facilities. The hospital ship should be the medical store ship of the fleet, and the fleet surgeon and other medical officers should keep in close touch with the hospital ship. He suggested the advisability of the organization of a medical society in the fleet, with the headquarters on the hospital ship. Junior medical officers should be detailed to serve for short periods on the hospital ship. He then discussed the final disposition of the sick, neutrality, the preparations for battle, the station of the hospital ship during battle, the importance of accurate and complete records and the final disposition of the wounded.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Thirty-fifth Annual Meeting, held at St. Louis, Oct. 12-14, 1909

(Concluded from page 1677)

Stricture of the Male Urethra

Dr. E. O. Smith, Cincinnati: Stricture of the urethra is an abnormal narrowing of some part of that channel which interferes with the free outflow of urine, due either to muscular spasm or to organic changes in the walls of the urethra. Abnormal narrowing of the external meatus should be divided very carefully. If cut too widely the patient will be left without projectile force. Spasmodic contraction of the urethra is usually due to acid urine, sexual excesses, fissure of anus, hemorrhoids, pin worms, cantharides, turpentine, etc. Strictures following traumatisms are much more stubborn to treatment and the band of scar tissue may have to be dissected out through an external incision. The popular idea that a rapid cure of gonorrhea causes stricture is not based on facts, but, on the contrary, the longer the duration of the gonorrheal inflammation the more liable is the patient to have a stricture. In fact, it is the exception for a urethra to become absolutely normal after one prolonged attack of specific urethritis. The urethra behind the constricting band becomes dilated, a pouch is formed which is a most excellent container and incubator for the germs of sepsis, which may lead to periurethral abscess and possibly urethral fistula. All this argues for an early treatment of stricture. Stricture is suspected when there is gleet, frequent micturition with a tardy beginning of the stream, dribbling after urination, with possibly some hypogastric pain. In examining for stricture great care and gentleness must be practiced, otherwise a false passage may be produced. Treatment is both general and local, and diet bland and not stimulating. Alcohol and tobacco are to be excluded, and sexual excesses avoided, and also exposure to cold and wet. Local treatment is that of gradual dilatation. Begin with the largest sound or bougie that can be easily passed; this may be only a filiform. The size of the sounds used is gradually increased. Treatments should be every four or five days in the beginning, with careful attention to surgical cleanliness. Urethral chill and shock can usually be prevented by giving the patient 10 grains of quinin and 5 drops of tincture of aconite about 20 minutes before the treatment. Epididymitis may, but seldom does, follow the passage of a sound. Strictures that do not yield to the gradual dilatation treatment are the exception. Internal urethrotomy should not be attempted except by those skilled in genitourinary surgery, as there is a possibility of doing great damage. External urethrotomy is seldom necessary in the treatment of stricture, other than those due to traumatism.

Burns

Dr. A. H. Barkley, Lexington, Ky.: Burns are the most frequent injury in civil life, cause the most agonizing suffering, and frequently condemn the patient to life-long mutilation of the most repulsive character. The severity of a burn depends on the character and degree of the heat, the length of time it is applied and the thickness of the cutaneous surface. A man, aged 56, an engineer, was burned by hot water and steam. He is 5 feet 10 inches and weighed 160 pounds at the time he was injured. He has nineteen square feet of skin on his body. Of this ten square feet were burned off, in four square feet the burn was of the third degree. Recovery was complete. The interesting points in the case are the area of skin burned, absence of contractures, no complications and healing without skin-grafting.

Treatment of Some Forms of Neuralgia by Deep Injections

Dr. D'Orsay Hecht, Chicago: My first patient was injected Nov. 20, 1906, and my last Sept. 30, 1909. During the period between these dates I have injected forty-eight patients with tic douloureux; eight besides this number were rejected because they were unsuited for this treatment. In all cases the diagnosis was made on the strength of the short, sharp paroxysms of pain so characteristic of the condition, and after careful inquiry into all conditions of the teeth, jaws, mouth, Gram-positive diplococcus was obtained from spleen, heart's blood, lateral ventricle of the brain, cerebrospinal fluid, throat and middle ear. This organism resembles in morphology and cultural characters the coccus described by Giersvold and also by Fox.

Microscopically the lesions in every case have resembled each other: (1) Congestion of vessels, especially those leading to anterior horns. (2) Perivascular infiltration of polymorphonuclear and mononuclear cells, the latter being both lymphoid and endothelioid in type. (3) Infiltration of pia and nerves running from anterior horns. (4) Necrosis of gray matter of anterior horns, especially the ganglion cells, with diffuse infiltration of polymorphonuclear and mononuclear cells. (5) Hemorrhages into gray matter of anterior horns. (6) Thrombosis of vessels in region of hemorrhages (seen only in Case 3). (7) Dilated lymph channels. (8) Occasional infiltration along lines of vessels extending into base of brain and also posterior horns of cord.

Dr. A. J. Chesley, Minneapolis: The Minnesota State Board of Health laboratory has received for examination specimens from 24 cases of poliomyelitis. Spinal fluids were sent in from 16 cases, but 5 showing no growth and 4 being badly contaminated, only 7 were suitable for investigation. From 6 a Gram-positive diplococcus, corresponding in every detail to the description of Giersvold's diplococcus given by Fox, was obtained in pure culture and further experimentation is now in progress. Hearty cooperation of physicians is urged in obtaining nose and throat cultures, spinal fluid, blood, etc., for examination from every case, and in securing permission for post-mortem examinations to be done by competent pathologists as soon after death as possible, that every facility may be had in the effort to determine the cause of this disease, and a specific remedy for its treatment or prevention.

Dr. W. A. Jones, Minneapolis: Eight years ago I saw about 12 cases of general paralysis which agreed closely with the epidemic of the present time. I called them simple neuritis. I believe, as has been suggested, that we are laboring under a misnomer in designating all these cases as anterior poliomyelitis, but, on the other hand, I do not agree with the suggestion that we ought to call everything of this nature anterior poliomyelitis.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Eighteenth Annual Meeting, held in Washington, D. C., Oct. 5-8, 1909
(Continued from page 1683)

The Venereal Peril

Lieut.-Col. Henry I. Raymond, U. S. A., based his paper on "The Eradication of Specific Urethritis from the Army by means of the 'K' package. Reenforced by Military Law and Discipline," on the following postulates:

Specific urethritis is the cause of more non-effectiveness in the army than any other one disease, the venereal diseases alone being responsible for a non-effectiveness equal to the loss of the services of an entire regiment for every day in the year, as shown by Col. John V. R. Hoff, U. S. Army, in his paper on "The Venereal Peril" (read by title).

Soldiers will expose themselves to venereal infection as long as human nature remains unsanctified. Moral suasion alone is inadequate to effect the desired revolution.

To effect escape from the physical ills of a sinful practice is a legitimate end of sanitary endeavor. It is not encouraging vice. The young man who avoids promiscuous intercourse from principle will not be misled through proffered immunity from infection.

A rational method of prophylaxis or prevention of specific urethritis has been devised, its general adoption in the army requiring the enactment and enforcement of a new military regulation making the contraction of gonorrhea a military offense.

There were issued to 576 individual enlisted men out of a garrison of 1,800 who applied for them at Fort Sam Houston, Texas, "K" packages. Of this 576, all of whom supposedly exposed themselves to the possibility of infection, in no case in which the remedy was intelligently applied, did it fail in efficacy. That portion of the garrison which did not make use of the package presented 66 cases of gonorrhea.

Those who did not use the "K" package and who contracted gonorrhea were wilful and neglectful, those who used the package and contracted gonorrhea were indifferent and careless; both classes were proper subjects for military discipline.

When there was no rational method of preventing the disease the contracting of gonorrhea was properly considered not a military offense, but now it may be viewed from a different standpoint.

So strong is the evidence that the "K" package, intelligently applied, will prevent infection, that no exemption should be made, but the unfortunate victim who may claim to have made use of the preventive should be held to have been negligent in its application if not untruthful in his allegation.

Weekly inspections should be made for venereal disease, and any attempt at concealment should be regarded as an aggravating circumstance before the summary court.

The weakest link in the chain of prevention of venereal disease in the army is the lack of a feeling of personal accountability on the part of the enlisted man, fostered by a sense of security from punishment for physical disablement through his own misconduct or through his indifference to rational preventive measures intended to secure his immunity from the ill consequences of his immoral acts.

Disease and Battle Casualty

Major Louis Livingston Seaman, U. S. V., stated that in most of the great wars of history three-fourths of the mortality has resulted from disease and only one-fourth from battle casualty. Most of this loss is preventable and constitutes a crime against humanity and patriotism. Service in six campaigns has convinced Major Seaman of the utter inadequacy of the medical departments of nations, with one notable exception. When it is remembered that this department combats the enemy that kills 80 out of every 100 that die in war, and that all the other machinery of the army kills but 20 per cent., and also that the medical department with its small numbers and limited authority, has to fight the invalidism that sometimes renders an army ineffective before the enemy, one is forced to the conclusion that the situation demands medical reform.

In order to focus the attention of military sanitarians on this subject, Major Seaman has offered a prize of $500, open to the world, in any language, for the best essay on the following subject: "What Should Be the Organization and Status of the Medical Department of Any Army, in Order that its Sanitary and Hygienic Conditions May be Maintained at their Highest Efficiency, so that in the Emergency of Battle, its Units May Best Respond to the Call of its Commanders?" The award of this prize will be made by the Executive Committee of the Seventeenth International Medical Congress, which meets in London, in 1912.

Care of Wounded in Ships

Medical Inspector Bunzo Tomatsuri, Imperial Japanese Army, believed that all surgical interference should be aseptic. Space should be provided in ships of war for original surgery, with possibility of uninterrupted communication by means of elevators and ladders. The greatest care should be taken of the wounded after first aid has been rendered. The provision for transportation and subsistence of the wounded still leaves much to be desired. He recommended the use of sandbag splints for immobilization.

Organization of Naval Medical Department

Medical Inspector Lloyd W. Curtis, U. S. N., discussed the organization of the medical department and the sanitary service of the fleet under present conditions, and described the organization which in his opinion would best meet the requirements of the fleet in view of further expansion, and render the most efficient service both in peace and war. He gave an outline of the duties of medical officers, the medical personnel of the fleet and their duties, the relations of the medical department to line officers. The office of fleet surgeon at present answers no particular purpose.

Best Training for Medical Officers

SURGEON CHARLES F. STOKES, U. S. N., who considered the question of what should constitute the best training for medical officers, the hospital corps and the ambulance parties of the fleet for sanitary service and as aid to the wounded in time of peace and war, insisted on previous service in civil hospitals and a rigid and exacting examination. He finally believed in the unification of action through the medium of postgraduate instruction in the Naval Medical School. The keynote of instruction in the school should be the cultivation of the senses, and independence of the laboratory and the *x*-ray. The association of naval medical officers with civil practitioners is inspiring. The hospital corps should be intelligent men. The advent of female nurses has made a great change and a signal advance in naval hospital conditions. MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Thirty-fifth Annual Meeting, held at St. Louis, Oct. 12-14, 1909

(Concluded from page 1677)

Stricture of the Male Urethra

DR. E. O. SMITH, Cincinnati: Stricture of the urethra is an abnormal narrowing of some part of that channel which interferes with the free outflow of urine, due either to muscular spasm or to organic changes in the walls of the urethra. Abnormal narrowing of the external meatus should be divided very carefully. If cut too widely the patient will be left without projectile force. Spasmodic contraction of the urethra is usually due to acid urine, sexual excesses, fissure of anus, hemorrhoids, pin worms, cantharides, turpentine, etc. Strictures following traumatisms are much more stubborn to treatment and the band of scar tissue may have to be dissected out through an external incision. The popular idea that a rapid cure of gonorrhea causes stricture is not based on facts, but, on the contrary, the longer the duration of the gonorrheal inflammation the more liable is the patient to have a stricture. In fact, it is the exception for a urethra to become absolutely normal after one prolonged attack of specific urethritis. The urethra behind the constricting band becomes dilated, a pouch is formed which is a most excellent container and incubator for the germs of sepsis, which may lead to periurethral abscess and possibly urethral fistula. All this argues for an early treatment of stricture. Stricture is suspected when there is gleet, frequent micturition with a tardy beginning of the stream, dribbling after urination, with possibly some hypogastric pain. In examining for stricture great care and gentleness must be practiced, otherwise a false passage may be produced. Treatment is both general and local, and diet bland and not stimulating. Alcohol and tobacco are to be excluded, and sexual excesses avoided, and also exposure to cold and wet. Local treatment is that of gradual dilatation. Begin with the largest sound or bougie that can be easily passed; this may be only a filiform. The size of the sounds used is gradually increased. Treatments should be every four or five days in the beginning, with careful attention to surgical cleanliness. Urethral chill and shock can usually be prevented by giving the patient 10 grains of quinin and 5 drops of tincture of aconite about 20 minutes before the treatment. Epididymitis may, but seldom does, follow the passage of a sound. Strictures that do not yield to the gradual dilatation treatment are the exception. Internal urethrotomy should not be attempted except by those skilled in genitourinary surgery, as there is a possibility of doing great damage. External urethrotomy is seldom necessary in the treatment of stricture, other than those due to traumatism.

Burns

DR. A. H. BARKLEY, Lexington, Ky.: Burns are the most frequent injury in civil life, cause the most agonizing suffering, and frequently condemn the patient to life-long mutilation of the most repulsive character. The severity of a burn depends on the character and degree of the heat, the length of time it is applied and the thickness of the cutaneous surface. A man, aged 56, an engineer, was burned by hot water and steam. He is 5 feet 10 inches and weighed 160 pounds at the time he was injured. He has nineteen square feet of skin on his body. Of this ten square feet were burned off, in four square feet the burn was of the third degree. Recovery was complete. The interesting points in the case are the area of skin burned, absence of contractures, no complications and healing without skin-grafting.

Treatment of Some Forms of Neuralgia by Deep Injections

DR. D'ORSAY HECHT, Chicago: My first patient was injected Nov. 20, 1906, and my last Sept. 30, 1909. During the period between these dates I have injected forty-eight patients with *tic douloureux*; eight besides this number were rejected because they were unsuited for this treatment. In all cases the diagnosis was made on the strength of the short, sharp paroxysms of pain so characteristic of the condition, and after careful inquiry into all conditions of the teeth, jaws, mouth, nose, and accessory nasal sinuses, which sources are frequently responsible for pain which may quite closely simulate the disease. One must be mindful of the fact that tumors involving the fifth nerve, as well as syphilis and migraine, can give rise to pains that may simulate trifacial neuralgia. In many of the cases external skiagraphs were taken, and when these were felt to be unsatisfactory or unreliable, intrabuccal film skiagraphs were supplemented for the purpose of eliciting better detail, thereby affording a better means of localizing possible dental or oral sources of irritation. Among the rejected cases were those in which pain was caused by the presence of abnormal dental conditions, post-influenzal nasopharyngeal infections, sinus disease and hysteroid conditions. In point of therapeutic results, 32 patients were distinctly benefited, 8 were improved, 5 were unimproved, and 3 were aggravated. Of the 32 benefited, 1 patient was free for 1 year and 8 months. The shortest free interval has been 2 weeks. Recurrences have varied, in the successful cases on an average of 1 year. Some have returned for reinjection on the first reappearance of pain in 4 months, some 6, some 10 months, some 1 year, some 16 and 18 months. The variability is accounted for by the personal equation and the accuracy with which the alcohol was deposited in, at or near the nerve. In the entire series the patients required from 1 to 5 injections, this number sufficing for a permanent cure in the non-symptomatic neuralgia. An 8 per cent. salt solution of body heat injected in the amount of from 90 to 120 c.c. has seemed to act to better advantage than lesser amounts of different temperature.

What Women Should Know in Regard to Uterine Cancer

Dr. J. Henry Carstens, Detroit: I have suggested that the medical profession agitate this subject in the lay press and on every occasion talk cancer. The physician should talk about it in order to arouse the public as to its importance, because it is a great menace. I have suggested to the members of the Michigan State Board of Health that they get up a circular which should be in the hands of every woman in the cancer period of life. This circular should be in the possession of county societies and of every physician and should be given to every woman in the cancer age. The menopause comes on gradually, rarely suddenly. It is not preceded by excessive flowing, or discharge, or pain in a healthy woman. By the cancer period is understood those years after forty, although rarely it may occur earlier. The first symptoms of cancer are: 1. Profuse flowing, even if only a day more than usual. Flowing or spotting during intervals or after the use of a syringe or the movement of the bowels. 2. Leucorrhea, if not existing previously. If existing, but becoming more profuse, watery, irritating or producing itching, it is a very suspicious symptom. 3. Loss of weight if no other cause is apparent. Pain in the region of the uterus, back or side. If any of the above symptoms occur after the age of forty or thirty-five a woman should seek prompt relief and insist on a thorough investigation of the cause and prompt treatment. Cancer is always at first a local disease and can be removed if early recognized, and an absolute permanent cure brought about.

Problem of the Insane and the Defective

Dr. L. M. Crafts, Minneapolis, read a paper on this subject which embodied a consideration of past methods of care or neglect of these conditions by society, the present lines of care and nurturing of them, enabling their more frequent and prolonged survival and activity, including procreation. He also took up the conditions in the present social state tending to greater strain on the nervous system, with the increasing lines of neuropathic heredity thus engendered. His paper dealt with the various state and national statistics bearing on the question and pointed out the present absolute lack of regulation or control of the free activity of these classes, in producing a posterity. He offered suggestions for advisable legislation for effective control of such individuals.

Reflex Neuroses Arising from Nasal Abnormalities

Dr. J. A. Stucky, Lexington, Ky.: Six salient points, as given by Ziegler, should be borne in mind when searching for reflex neuroses, and to these I would add a seventh: 1. Eye and nose must first of all be thoroughly examined and excluded or accepted as exciting cause. 2. Careful differentiation should be made of those reflexes manifested in common by the eye and nose. 3. Eyestrain from whatever cause, whether ametropia, subnormal accommodation or intranasal pressure, should be corrected to exclude the eye as a factor. 4. Pressure contact in the nose in every instance must be relieved. 5. Every obstruction to free breathing in the superior part of the nose should be removed. 6. Recurrence of any reflex neurosis demands reexamination, renewed search for and correction of original exciting cause. 7. Lithemic conditions, faulty intestinal metabolism of whatever type, must be corrected and deserve careful consideration in every reflex neurosis whatever be the exciting cause.

Acute Dilatation of the Stomach

Dr. Edwin Walker, Evansville: The treatment of acute dilatation of the stomach consists of prompt evacuation of the stomach by the stomach tube, followed by copious lavage. It would be an excellent practice in all postoperative cases in which vomiting is prominent to resort to this measure. In order to release the pressure on the duodenum the patient should lie on the abdomen, with the foot of the bed elevated or, in extreme cases, in a knee-chest position. It is astonishing in grave cases to see the prompt relief given by these measures. The lavage should be repeated when the fluid reaccumulates or if the condition of the patient does not improve. Strychnin and physostigmin have been given. Rectal feeding should be given.

Muscle Rigidity: An Important Physical Sign of Disease Within the Chest

Dr. F. M. Pottenger, Monrovia, Cal.: Muscle rigidity is a feeling of resistance noticed on palpating the muscles overlying inflammatory conditions of the pleura and pulmonary parenchyma, due to (1) acute spasm of the muscles when the inflammatory process is acute; (2) pathologic change in the muscles when the inflammation is chronic. Muscle rigidity affects both the superficial and deep muscles. It is easily found when the inflammatory process is acute, for then the muscle stands out in acute spasm, or when the process is chronic in character and wide in extent the pathologically changed muscles are easily felt. It is difficult to find if the process is small in extent and not very active. It is important as a differential point in diagnosis between an acute and quiescent process in the lung. If the muscles are in spasm my experience would warrant the statement that the underlying process is acute. Muscle rigidity is not only a valuable sign, but it offers a rational explanation for one other sign, thus limited motion, lessened respiratory murmur, harsh respiratory murmur, prolonged expiration, ankylosis of the costosternal joint, curvature of the spine and increased resistance and slightly altered pitch on percussion.

Prophylaxis of Pellagra

Dr. C. H. Lavinder, Washington, D. C., in a paper on this subject reviews very briefly the theories as to etiology and discusses two points: first, the communicability of the disease, and, second, the practical application of its alleged relation to the use of spoiled corn as a food stuff. He considers that our experience in the United States is too limited for us to base conclusions thereon and that it would be unwise to reject the accumulated observations and deductions of other able men in other countries whose experience has been so much wider and fuller than our own. Since practically all observers agree that the disease is not communicable, and since quarantine measures are not in force against it, he thinks it is not necessary in the present state of our knowledge to adopt quarantine measures. So far as its relation to spoiled corn is concerned, he admits that much of the evidence is unsatisfactory, but since practically all theories of the disease take corn into more or less essential consideration and since Italy, in her determined fight against pellagra, has based most of her procedures on this theory and is claiming a fair share of success, we cannot at present do otherwise in our prophylactic measures than recognize some relationship between corn and pellagra.

COLLEGE OF PHYSICIANS OF PHILADELPHIA

Regular Meeting, Oct. 6, 1909

The President, Dr. James Tyson, in the Chair

Extrasystolic Arrhythmia Simulating Heart-Block

Dr. George W. Norris: The paper is a report of four cases, one of which presented very unusual and perplexing features. This case was first believed to be one of auriculoventricular heart-block, but on careful study proved to be one of extrasystolic arrhythmia. The curious feature of the case was that the patient's peripheral pulse rate would suddenly drop from 80 to 40. This change could for a considerable period of time be brought on at will by a few simple procedures, such as a rapid change of posture, taking a deep inspiration, or compressing the abdomen. Later, in the course of the disease, this tendency became less marked, and a typical pulsus alternans developed. The post-mortem examination revealed well marked arteriosclerosis, with fatty and fibroid changes in the heart muscle.

DISCUSSION

Dr. William Pepper: An interesting point to me is the lack of our ability to feel these small extrasystoles. Even with the finer instruments, at times, one cannot perceive them at the wrist or in the brachial artery. I do not say that we are able to tell whether in the small beats the valves open or not, but I think that when we are unable to detect by instrumental means any wave in the peripheral arteries, then probably the aortic valves have not opened.

Dr. S. Solis Cohen: I should like to ask Dr. Norris to test in various ways what has been well termed the reserve force of the heart, to include the effect of local applications of heat and cold over the precordium. A rough but ready way of determining the amount of good cardiac muscle remaining is to note by the finger the response of the heart to momentary applications of heat followed by cold. When the response is good the prognosis is rather favorable. When this application increases the arrhythmia the prognosis is bad.

Dr. Robert N. Willson, Jr.: In studying certain problems in tuberculosis of the guinea-pig I noticed on taking out the heart that when it was exposed to the air the pulsation which almost immediately after removal of the heart from the pig assumed the character of a fibrillary tremor, again changed its nature. The ventricular contractions stopped almost completely, and the auricular systoles continued their rhythm. Then the auricular contraction seemed to cease and the ventricular resumed and later again discontinued. Then for a time and occasionally both were synchronous. Finally, before the contractions stopped altogether, the ventricular systoles gradually increased in power and extent, and the contractions seemed to recede toward the auricle and then toward the great sinus and then disappear. If these phenomena are produced in any such way in the human body in disease, it must needs be that very trifling alterations in the conditions of the body, chemical changes, etc., assume great importance in alteration of the normal beat. This would account for many of the conditions which we now try to explain along chemical lines. If the human heart acts as does the guinea-pig's, then I think the conditions in disease are not understood. We know simply that dissociation of the auricles and ventricles is possible. The causal factors and the governing laws still remain obscure.

Dr. John B. Roberts: I have been interested in watching the intermission of the pulse in two boys who have had measles. In one the intermittent pulse was present for a year and a half after the attack and finally diseappeared. My explanation was that there was a mild myocarditis. In the other at the time of the intermission of the pulse I have noticed the extra beat of the heart, suggesting the motion of a fish lying in the bottom of a boat. This, I suppose, was the extrasystole. The boy seems to be better under belladonna than under digitalis, although the improvement may be due to the fact that he is regaining the general tone of the muscle and that the irritability is subsiding under the increased time rather than from the belladonna.

Dr. A. A. Eshner: This case emphasizes my view that there is a relation between the varied forms of myocardial degeneration that for convenience's sake we classify clinically as myocarditis and the condition of heart block. It seems to me that degeneration of the heart muscle, whether fibroid or gummatous, not necessarily involving the auriculoventricular conducting bundle of His, may cause degeneration in conductivity or contractility or in the other attributes of the muscular wall of the heart and give rise to disorders of rhythm that we include under the general designation of arrhythmia, and of which heart-block must be considered as an extreme type. I should imagine that the underlying factor in the circulatory variations was the state of the myocardium and that by reason of its inefficiency it was unable to compensate for the increased burden thrown on the heart by reason of the increased blood-pressure.

Dr. G. W. Norris: It has been repeatedly shown that partial ligation of the aorta in animals will produce extrasystoles. It is quite common to find arrhythymias in young children, particularly after febrile attacks. The type is better designated as sinus arrhythmia. It is probably due to over-action of the vagus nerve affecting the sinus rhythm. Therefore, when belladonna, which depresses the vagus nerve, is given the arrhythmia disappears. While I do not mean to indicate that we have by any means cleared up the whole question, taking up the matter on the basis of the myogenic theory, and considering the five functions of the heart muscle independently, we are able to theorize just as Ehrlich's hypothesis of the blood complement has furnished the bacteriologist with a working basis. Dr. Eshner, in his remarks about blood pressure, stated what I had intended to say.

Spasm of the Arteries and Report of a Case of Vasomotor Neurosis

Prof. Paul Lazarus, of Berlin, presented, by invitation, this paper. Professor Lazarus spoke on the vasomotor neuroses, and dealt with functional in contradistinction from anatomic disorders. Under ordinary conditions the circular muscular fibers of the arteries predominate in action over the longitudinal fibers, thus maintaining normal vascular tone. This may be increased by a variety of influences acting from without or from within. Vasomotor neuroses may be of two types, hypertonic or hypotonic, or there may be a combination of the two. Among them may be included migraine, exophthalmic goiter, sclerodactyly, scleroderma, Raynaud's disease, erythromelalgia, paresthetic meralgia, dermographism, angina pectoris, pseudoangina, Stokes-Adams syndrome, paroxysmal hemoglobinuria and hematuria, the crises of locomotor ataxia and vasomotor ataxia. He cited an instance in which arteriosclerosis developed in the train of long-continued increase in blood-pressure apparently of functional origin. He cited another instance in which in the sequence of emotional shock pallor, cyanosis, atrophy and gangrene developed in the upper part of the body, while hyperemia and hypertrophy developed in the lower part. He pointed out that no functional disturbance could take place without vasomotor or nutritive change.

DISCUSSION

Dr. S. Solis Cohen: There seem to be three elements in the origin of vasomotor disorders: (1) A constitutional liability of the patient; (2) an exciting cause; (3) the point which to me is most obscure—a local determinant. Just why the same patient should have at one time migraine; at another a condition simulating hepatic colic, at another hemianesthesia or asthma or urticaria or circumscript edema of the skin or mucous membranes, is yet to be determined. In some instances, a very slight mechanical force, scarcely to be termed trauma, determines it. At other times the exciting agent, a toxin or thermic change, acts locally, as when the hand plunged into ice water exhibits Raynaud's phenomena or intestinal fermentation gives rise to enteralgia. I do not know why one of my patients who has recovered from Graves' disease should be troubled with recurrent spasm of the temporal artery so that vessel can be seen becoming more distended and more tortuous above the point of constriction, this being accompanied with intense pain which lasts for a minute or two and which can be relieved immediately by the administration of nitroglycerin to relax the spasm, nor do I know why hemoglobinuria follows application of ice to the loins, or to the feet, as happens in another patient. Evidently there is a local determinant in each case. The important point is that we should diagnosticate the individual rather than the attack.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

CALIFORNIA: Los Angeles, December 7. Sec., Dr. Charles L. Tisdale, Butler Bldg., San Francisco.

DELAWARE: Regular, Dover, December 14; Homeopathic, Wilmington, December 14. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

IOWA: State House, Des Moines, Dec. 7-9. Sec., Dr. L. A. Thomas.

KENTUCKY: The Armory, Louisville, December 14. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: 1211 Cathedral St., Baltimore, December 14-17. Sec., Dr. J. M. Scot

PENNSYLVANIA: Philadelphia, December 14-17; Electic 4-17. Secretary of the Medical Counc larrisburg.

VIRGINIA: Lynch)r. R. S. Martin, Stuart.

Michigan May and June Reports

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the written examinations held at Detroit and Battle Creek, May 24-26, and at Ann Arbor, June 8, 1909. Besides the written examination a practical test in refraction was required. The number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75.

At the examinations held May 24-26, the total number of candidates examined was 62, of whom 57 passed, 1 failed, and 2 were conditioned. The papers for two candidates have not been completed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
American Medical Missionary College	(1909)	82.7, 83.6, 88.7, 89.6, 90.2, 91.5
Hahnemann Medical College and Hospital, Chicago	(1908)	76.7
Northwestern University Medical College	(1908)	85.3
Louisville and Hospital Medical College	(1908)	78.4
Kentucky School of Medicine	(1908)	81.4
University of Michigan, College of Medicine	(1890)	87.3; (1908) 88.7; (1909) 86.
University of Michigan, Homeopathic College	(1908)	86.3
Detroit College of Medicine	(1909)	77.6, 78.1, 79.3, 80.5, 81.3, 81.9, 82.1, 82.6, 82.9, 83.4, 83.7, 83.7, 84.1, 84.2, 84.3, 84.3, 84.4, 85.3, 85.4, 85.5, 86.4, 86.6, 87.5, 87.6, 87.7, 87.7, 88.3, 88.4, 88.5, 89, 89.5, 89.5, 89.9, 89.9, 90.
Detroit Homeopathic College	(1909)	76.9, 78.1, 78.5, 78.9, 80.7
Eclectic Medical Institute, Cincinnati	(1907)	81.2
Jefferson Medical College	(1904)	78.5
Imperial University, Warsaw	(1904)	82.5
FAILED		
University of Michigan, Homeopathic College	(1908)	74
CONDITIONED		
Louisville Medical College	(1902)	*77
Detroit College of Medicine	(1909)	**79.1

* Conditioned in surgery.
** Conditioned in eye, ear, nose and throat.

At the examination held June 8, the total number of candidates examined was 79, of whom 70 passed, 1 failed and 3 were conditioned. The papers for five candidates have not been completed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
American Medical Missionary College	(1907)	75
University of Louisville	(1908)	86.6
Rush Medical College	(1909)	86.7
University of Michigan, College of Medicine	(1909)	78.4, 79.8, 80.7, 81.8, 82.6, 82.8, 83, 83.3, 83.5, 83.8, 83.9, 84, 84.1, 84.2, 84.2, 84.2, 84.4, 84.7, 84.7, 84.8, 85.2, 85.2, 85.2, 85.3, 85.5, 85.5, 85.5, 85.9, 86.2, 86.7, 86.8, 86.8, 86.8, 86.8, 86.9, 86.9, 86.9, 87, 87, 87.1, 87.3, 87.4, 87.4, 88.1, 88.1, 88.3, 88.7, 88.7, 88.9, 89.2, 89.5, 89.5, 89.9, 90.7, 91.1, 91.7,
University of Michigan, Homeopathic College	(1909)	82.6, 85.1, 86.1, 86.2, 86.4, 87.1, 87.2, 87.4, 88.2, 88.8, 89, 90.3.
FAILED		
Kentucky School of Medicine	(1907)	71.5
CONDITIONED

Laval University, Quebec	(1904) 68.4; (1909)	74.7

Book Notices

L'Hypophyse et la Médication Hypophysaire. Par M. le Docteur Arthur Delille, Membre Adjoint de la Société Anatomique. Paper. Pp. 336. Paris: G. Steinheil, 1909.

The present volume is valuable not only because of the records of experimental work by Dr. Delille but because it contains a thorough review of the rapidly increasing literature of the subject. The conflicting views concerning certain phenomena are set forth, and an effort is made to reconcile the discrepancies, particularly those regarding the effects of hypophysectomy. The experimental work by Dr. Delille is concerned almost entirely with the effect of extracts of hypophysis when injected into animals and man during health and in disease. There is no discussion regarding the technic of operating on the gland. Dr. Delille discusses the experiments of Masay, which attempted to create for experimental purposes, by the administration of a so-called hypophysotoxic serum a condition analogous to that following surgical removal of the gland. This serum was prepared by immunizing guinea-pigs with an extract of hypophysis. He criticises the value of the conclusions drawn because no account was taken of the possible effect of the serum on the rest of the body, particularly the other glands, but he admits that work by this method would be valuable if careful observations were made concerning the effects of the serum. In the essential points Delille is in harmony with Cushing (The Journal, July 24, 1909, liii, 249), but he differs in several details. He finds that in animals an anterior lobe extract causes moderate hyperactivity of the hypophysis and thyroid, but Cushing states that it does little or nothing.

Some of Delille's conclusions are especially interesting, as for example, the signs and symptoms of diminished and increased activity of the gland. He sums up those of hypophyseal insufficiency and dyshypophysism as follows: hypotension, tachycardia, distressing sensations of heat, profuse sweats, oliguria, anorexia, asthenia, disturbances of nutrition (loss of flesh; obesity in certain cases, trophic changes, etc.), psychic troubles, insomnia, disturbed growth (physical and mental backwardness), diminution of resistance to intoxications, special signs of intracranial compression due to pituitary tumor. The evidences of hyperhypophysism he says are: hypertension, polyuria, glycosuria, troubles of nutrition (loss of flesh; often obesity, etc.); the number of blood-cells equal or above normal; hypertrophic processes of development (gigantism, acromegaly); psychic troubles, somnolence; nearly always a genital insufficiency; frequently hypothyroidism; and special signs of intracranial pressure due to pituitary tumor. Cushing states that polyuria, sometimes associated with glycosuria, is a somewhat characteristic symptom of hyposecretion of the anterior lobe instead of hyperhypophysism. Moreover, he regards adiposity as a more constant and more important sign of hyposecretion than does Delille.

Concerning the indications for hypophyseal medication Delille seems to hold perhaps too radical an opinion for the present state of knowledge when he makes the following statement: "The direct hypophyseal organotherapy will find its indication in every case in which one wishes to raise the arterial tension, slow the pulse, increase diuresis, suppress troublesome sensations of heat and profuse sweats, ameliorate the appetite and sleep, cause the disappearance of asthenia, attenuate certain psychic troubles, exercise a stimulating action on nutrition and development; in short, hypophyseal organotherapy will be prescribed in every case in which the certain or probable diagnosis of hypophyseal insufficiency shall be made. One should abstain from this medication with patients who have a hypertension."

As regards the administration of the extract Delille says: "One should use by preference the total extract, for it is, in equal doses, nearly as active as the posterior lobe; besides it is easier to prepare and consequently less expensive. The properties of the anterior lobe are still too mysterious to warrant the use of its extract in practice. The daily dose of the total extract which one should advise ought not to be more than that of half of one fresh gland of the beef, save in exceptional cases. The patient should be strictly watched in the course of the treatment; the arterial pressure should be taken regularly and one should depend on it to increase or diminish the doses, to suspend or to resume medication."

Lehrbuch der ~ Herausgegeben von Prof. Dr. J. Schwalbe, Price, 26 marks. Stuttgart: Verlag vor

The necessity for a special work on the disease of old age does not at first seem perfectly clear. While it may be argued that there is as much justification for a work of this sort as for one on diseases of children, most readers will feel that the peculiar problems presented by infant-feeding, the rapid progressive changes of infancy and childhood, the partiality of so many acute infectious diseases for childhood, and certain anatomic and physiologic peculiarities of the young, offer valid reasons for the existence of treatises on the diseases of children, which reasons do not quite have their counterpart when the maladies of old age are considered. One must admit, however, that certain characteristics of old age are worth emphasizing and perhaps even embodying in a special volume; one thinks at once of the regressive and atrophic changes in tissues, the vascular scleroses, the frequency of carcinoma, the vulnerability to pneumonia, etc.

These peculiarities are well brought out in this work. Of necessity, much that is not peculiar to old age is embodied. Perhaps we ought not to say of necessity, for we are inclined to think that had there been a liberal omission of much of the description that would apply to disease of all ages (which knowledge should be assumed as possessed by the reader), and if there had been more concentration of the peculiarities of the various affections in old age, the value of the book would have been increased.

Most of the articles are good, as the names of the writers would lead us to expect. Some of these writers are themselves old, but they write with the vigor of youth and the wisdom of advanced years. Some articles are unusually full, e. g., Hope-Seyler's on respiratory diseases, and Ortner's on typhoid fever. Fürbringer's article on prostatic hypertrophy is reasonably complete, yet carcinoma of the prostate is covered in half a page. Ebstein might appropriately have gone more into details on arteriosclerosis.

The book may be commended as thoroughly reliable, though we feel that the physician who needs help in the diagnosis of treatment of a disease in the aged, be it pneumonia, typhoid, gastritis or carcinoma of any organ, will be more apt to turn for help to his work on general medicine or to special works than to this book, which, after all, is much on the order of a compend of symptoms and signs of disease as seen in the old with the treatment.

Causes of Disability as Applied Under Accident and Health Insurance Policies. Designed for the Use of Insurance and Fraternal Examiners, General Practitioners and Students of Medicine, Attorneys and Corporations. By Charles Hamilton Harbaugh, M.D., Medical Director American Assurance Company. Cloth. Pp. 650, with illustrations. Price, $6. New York: The Spectator Co.

The average physician is sadly deficient in his knowledge of the laws of accident and industrial insurance and of the proper method of making examinations and writing out reports concerning his findings in this class of cases. The object of this work is to supply this knowledge; but on reading it one is impressed by the fact that it is apparently written in the interests of the accident-insurance companies rather than in the interest of the physician or of scientific medicine; invidious comparisons are frequently made between the life-insurance examiner and the accident-insurance examiner.

Physicians are urged to "develop themselves into adjusters for the companies they represent." "A doctor who adjusts for an accident-insurance company is so well intrenched with his company that it is almost an impossibility for another physician to secure any examinations from the company."

For all of this examining and adjusting and playing the interests of the company against those of the patient, the compensation is altogether inadequate, for it is stated that "accident-insurance companies seldom pay more than two or three dollars for each examination." That the advice given in settlement of cases is at times to the advantage of the company at the expense of what is just to the insured, is well shown on page 102, under "Diseases of the Brain." "When the diagnosis of an abscess of the brain exists and there is a history of a severe injury, such as a fracture of the skull or a bad concussion, it is best for an insurance company to effect an advance settlement with an individual who may be carrying an accident-insurance policy by allowing one or two months of this disability. Should an adjustment not be secured, the abscess may terminate in death, and if this occurs within ninety days from the date of the accident, the company may be liable for a death claim for the amount of the policy and this would be much more than if the above time of total disability had been paid.

"Insurance companies do not care to take chances on these cases and prefer to make a settlement in advance."

While the volume contains information of value to those engaged in this particular line of work, one cannot but be impressed by the fact that much of it is written from a biased point of view.

Text-Book of Hygiene. By George H. Rohé, M.D., Late Professor of Therapeutics, Hygiene and Mental Diseases in the College of Physicians and Surgeons, Baltimore, and Albert Robin, M.D., Professor of Pathology, Bacteriology and Hygiene, Medical Department Temple University. Fourth Revised Edition. Cloth. Pp. 582, with illustrations. Price, $3. Philadelphia: F. A. Davis Co., 1908.

This work, during the lifetime of Dr. Rohé, enjoyed not a little well-deserved popularity, which, after his death, for lack of revision, suffered partial eclipse. It now appears edited by Dr. Albert Robin, assisted by special writers on such topics as military, naval, school and personal hygiene and quarantine.

The editor has had an arduous task before him, that of adding, subtracting and correlating in such a way as not to detract from the ensemble and style of the book as Rohé left it. The result is perhaps as satisfactory as could be attained by any means (short of radical rewriting of the whole book). There might have been a more general modernizing of much of the sources of statistics and opinions throughout the book; this criticism is particularly applicable to the retention of Pettenkofer's theory in references to typhoid fever and Asiatic cholera. The pruning-knife, too, might have been more vigorously used in several places in the chapters dealing with air, soil, antiseptics and disinfectants and the infectious diseases.

A few typographic errors have crept in, noticeably in the disarticulation of the last paragraph on page 563 from its context at the end of the second paragraph on page 562. The photographic reproductions, Figures 7, 46, 47 and 50 are very indistinct, owing, doubtless, to the unsuitability of the paper for this sort of work. Figure 45 is reversed. The book in its general make-up is pleasing and its contents well within the bounds of accuracy.

The Practical Medicine Series. Edited by Gustavus P. Head, M.D., Professor of [illegible] Rhinology, Chicago Postgraduate Medical School. [illegible] RY. Edited by John B. Murphy, A.M., M. [illegible] Surgery in Northwestern University, Chicag [illegible] th illustrations. Price, $2. Series 1909. [illegible] Publishers.

The volume on General Surgery of the Practical Medicine Series for 1909 is well up to the high standard of excellence which has characterized its predecessors. The accomplished editor of this *multum in parvo* has so thoroughly reviewed the surgical literature of the past year that very little of importance has been omitted. We can heartily endorse and commend to the particular notice of hospital authorities the remarks of the editor on the necessity for reform in the methods of administration of anesthetics. The administration of anesthetics by persons without special training, as practiced to-day in many of our hospitals, is, in the light of modern knowledge of the subject, almost criminal. While the greater part of the book is devoted, as might be expected, to the surgery of the abdomen, in which wonderful progress is to be noted, the whole field of general surgery is well covered. With its full index this little volume is a valuable accession to the library of either surgeon or general practitioner.

Suture of Arteries: An Experimental Research. By E. Archibald Smith, M.B., Ch.B., Victoria University, F.R.C.S., England. Cloth. Pp. 70, with illustrations. Price, 90 cents. New York. Oxford University Press, 1909.

The paucity of literature in the English language on the subject of suture of arteries, the little that exists being mainly scattered in journals, has led Smith to prepare this little monograph. The first two sections are devoted to historical description of the various methods of operation and brief lists of cases in which they have been employed. The third and fourth sections are devoted to a description of the method of suture devised by the author, and an account of research work done by him. From his experimental work and the study of reported cases, Smith concludes that successful suture of blood vessels depends, under strict asepsis, on the bringing together of intima with intima with the minimal amount of suture exposed to the blood current. This, he believes, can be most certainly accomplished by a quilled suture method of his own device. The principal methods in vogue are clearly described and illustrated. The typography of the book is excellent, but it is to be regretted that the fairly complete bibliography is nearly two years behind the date of the preface.

Principles of Pharmacy. By Henry V. Arny, Ph.G., Ph.D., Dean and Professor of Pharmacy in the Cleveland School of Pharmacy, Pharmacy Department of Western Reserve University. Cloth. Pp. 1175, with 246 illustrations. Price, $5 net. Philadelphia: W. B. Saunders Co., 1909.

There are already in the field a considerable number of works on pharmacy, but the subject has by no means been exhausted. In the preface Professor Arny states that the "frank intention of this book is to explain the Pharmacopeia from its pharmaceutical standpoint. At the same time, however, the book disclaims all attempts to be a text-book in chemistry or botany."

Professor Arny treats the subject in seven sections or parts. In Chapter 1 of the first part the origin, history and scope of the Pharmacopeia are explained in detail. The later chapters of Part I are taken up with a description of the technic of pharmaceutical operations. Part II considers the official Galenical preparations and such others as are worthy of notice. In Parts III and IV the chemical relations of drugs are considered. The official pharmaceutic tests and assays are grouped together in Part V, a feature not found in other treatises on pharmacy, although an arrangement somewhat similar to this has been purposed for the next U. S. Pharmacopeia. The prescription in all its phases is considered in Part VI. Part VII is a manual of laboratory exercises involving all of the operations of practical pharmacy, and including exercises in equation-writing and chemical arithmetic.

A few verbal inaccuracies may be noted, but they are not such as greatly to impair the value of the work. While some might doubt the need of introducing the rudiments of physics and chemistry, the sections on these subjects will be of use to the practicing pharmacist whose preliminary training is limited. On the whole the book is well written and should prove particularly valuable to the student of pharmacy and even to the physician as a reference work.

[illegible] By May Cushman Rice, M.D., [illegible] in the Illinois School of [illegible] with illustrations. Price, $1. Chicago: L. I. Laing & Co., 1909.

For those who believe in electricity as a curative measure, Dr. Rice has written an epitome of the therapeutic indications for electrical treatment. She has given concise and definite information as to the action of different currents, including cataphoresis and electrolysis. After explaining the therapeutic value of the poles, Dr. Rice gives a simple method of polarizing a battery that will insure definite results. The cataphoretic application of thiosinamin is mentioned for dissolving scar tissue. The questionable value of the *x*-ray in the treatment of carcinoma is very sanely considered as a valuable adjunct to surgery and a boon to the sufferer of inoperable carcinoma. In Dr. Rice's remarks on fibroid she has overlooked the risk of using electricity without a microscopic examination, which alone will determine whether or not the tumor is malignant; neither is she concerned with the possibility of a secondary malignant growth developing in a fibroid tumor. In the treatment of acute inflammations, the question of the element of the phagocytic action of the blood is entirely ignored, and from the results which she has obtained in acute conditions, and the length of time requiring a symptomatic cure, the convalescent period does not seem to be shortened. The deductions offered as to the efficacy of electricity in cellulitis and salpingitis are not convincing, or in many respects scientific.

Medicolegal

Power of Claim Agent to Employ Physician

The Appellate Court of Indiana, Division 2, says that the case of Southern Ry. Co. vs. Hazlewood (88 N. E. R. 636), was brought by the latter, a physician, to recover the value of services rendered a brakeman injured in the company's service. The evidence showed that the brakeman was injured during the night and was taken to a place where he was examined by the company's regular surgeon, who at that time gave him no medical attention beyond prescribing a headache powder; that the next morning his father, a physician who lived at a distance, came to see him, and dismissed the company's surgeon, whereupon the plaintiff became the attending physician. A claim agent, or "assistant law agent," called on the injured employee the same morning. There was evidence that he told the brakeman to keep the plaintiff, and the company would pay for it. The brakeman was later removed to a hospital, where on at least two occasions, the claim agent inquired how he was getting along, told him to let the plaintiff continue his treatment, and that the company would pay the bill. The plaintiff testified that the claim agent said that the brakeman was dissatisfied with the company's surgeon, and that he wanted him to go ahead and look after him, and that he should rest easy about the bill: that the company would as soon pay him as any other physician, and for him to keep account of his bill, and the company would pay it. The plaintiff ordered a spinal brace for the patient of a surgical instrument house in Louisville and the bill was sent to the company's general superintendent and paid. The brakeman testified that the settlement was made between himself and the company by its agreeing to give him $5,300 and pay his hospital expenses and doctor bills.

The court holds that the first paragraph of the complaint, which was what is called a common count "for services rendered at the special instance and request of the defendant," was sufficient, as railroad companies may employ surgeons generally.

The company urged that the claim agent had no authority to employ a physician. But he had authority, the court says, to compromise the claim against it, and to minimize damages recoverable from it. The settlement which he made was adopted. The employment of a competent surgeon might be one step in minimizing such damages and in procuring such settlement. It was therefore germane to the employment. The company, having held him out as possessing authority, was in any event precluded from denying it.

The case of Louisville, etc., R. Co. vs. Smith, 121 Ind. 353, strongly relied on by the company, was not in point. The authority of a conductor and a claim agent rests on a different basis. The natures of the two employments are essentially different. The duty of the "assistant law agent" was to visit injured persons, and to settle or to compromise with them. The employment of a physician is reasonably incidental to those duties, and whether he acted within the scope of his authority was a matter of proof.

The promise of the railroad company to pay the plaintiff was not within the statute of frauds, so as to be required to be in writing, for two reasons: (1) The debt was the debt of the company; (2) where a promise is made to a debtor to pay his debt to a third person, and sufficient consideration has passed between the debtor and promisor, an action may be maintained without the discharge of the original debtor.

A judgment for $196 in the plaintiff's favor is affirmed.

Evidence and Certainty Required to Sustain Malpractice Cases

The Supreme Court of Oklahoma holds, in Kernodle vs. Elder (102 Pac. R. 138), that, in suing a physician for malpractice in setting and treatment of a fractured limb, where there is no guaranty of cure or contract for extraordinary skill, and where the evidence fails to show that the results are not such as usually and ordinarily result in such cases where treated by an ordinarily skilful physician using ordinary care, then there is a failure of proof, and the plaintiff is not entitled to recover. Where in such a case it is apparent from the record that the claim of the plaintiff cannot be sustained, on reversal the court will not remand for new trial, but will direct a dismissal.

There are no classes of cases, perhaps, which go to juries, or, indeed, with which lawyers and courts are called on to deal, the court says, where results are so uncertain and so frequently unsatisfactory as cases involving damages against physicians for alleged malpractice in their efforts to alleviate the ills to which human flesh is heir. It is nearly always the defendant's judgment which is on trial; and on the hearing the jury and the parties are all sitting and speaking after the fact, while the unfortunate physician when he acted was perhaps required by the conditions to grope, deliberate, and often speedily act, and always before the fact. After he has acted and the results are different than he desired or expected, and different than were expected or desired by the patient, if a suit is brought, the physician is confronted with all of the after-acquired knowledge, and his responsibility is weighed from that standpoint rather than from the true one. A preponderance of the evidence in cases of this character is sufficient to sustain a plaintiff's cause. No more should be required, and no more is required; but it should be certain on the part of the court and the jury that they are acting from actual evidence before them, properly referable to the cause, and that the judgment, when against the physician, is based on such evidence, and not on bias, conjecture, or inference.

In this case the plaintiff claimed that he fractured the bone of his right hip joint, and that the defendant negligently and unskillfully diagnosed the difficulty, in that he dressed and bandaged the limb as if the break were between the knee and the hip, and as though the fracture were in the vicinity of the knee, and that by reason of this error on his part the fracture itself was left wholly unattended and uncared for. The evidence showed that the plaintiff, who was a man of the age of 56 years and of fairly good health and activity, fell on the ice and fractured the femur bone of his right leg at or near the neck. He called in the defendant to treat him, and the defendant arrived in about two hours after the accident, placed the plaintiff under the influence of chloroform, and made an examination. The plaintiff and a number of other witnesses, members of his family and neighbors, testified that the defendant informed him and them that the limb was fractured at a place above the knee, between it and the upper part of the femur, perhaps about the middle. It also appeared that the defendant applied a "Buck's extension," which consisted of, in this case, a splint in the shape of a board, attached to the limb on the under side, to which was fastened a rope which extended to a window frame, with a 5½-pound iron attached, for the purpose of tiring and extending the muscles to bring the broken parts of the bone in apposition. The physician remained with the plaintiff all of that night, and on the morning of the second day thereafter he returned, bringing with him what is commonly known as a "Hodgen splint," an appliance which he had made, consisting of an iron, bent much in the shape of a hairpin, the two sides laced together with webbing or cloth, and of about the length and shape of the leg. Into this the limb was placed with the foot near the loop, the open end being toward the body, the inside piece being about 10 inches shorter than the outside piece. This entire frame was then swung about 2 inches clear of the bed, allowing the limb to lie in this splint, which was attached to a pulley from the ceiling or window ledge by ropes or cords. That in this condition the plaintiff remained in bed about three weeks, during which time he was waited on by the physician. The plaintiff testified that his limb was left by this treatment in a weak or stiff condition in the hip, which interfered with its use; that it hurt him in walking, and he stated: "I cannot use it as well as I could before it was hurt; it is stiff, and the muscles won't expand;" also, that he could not walk without the use of a cane or crutch.

The plaintiff also stated that after the treatment by the defendant he had applied to two local physicians for treatment, one of whom testified that he made an examination of the limb and was present when the same was examined with the *x*-ray. That the examination revealed an impacted fracture at the neck of the femur, the result of which, he stated, necessarily shortened the limb. He further testified that in a case of this character it was very likely that treatment would not produce the best results, and that the limb would be shorter than its normal length.

From the testimony of the local physicians it appeared that the injured limb was from 1 inch to 1½ inches shorter than the other, and from this evidence no other inference could be drawn than that this was as good a result as could be reasonably expected, considering the age and condition of the plaintiff. At all events, there was an absolute lack of any evidence, the court says, showing that in cases of this character, under any kind of treatment, the limb is ever perfect afterward or equals in length the uninjured limb. In this case the burden was not on the defendant to show that the plaintiff's limb was in as good condition as medical science and skill could place it after its injury, but the burden was on the plaintiff to show that it was not. This, in the court's judgment, he totally failed to do.

Should it be shown by the evidence that the limb which the plaintiff had was not such a limb as a physician of ordinary skill and using ordinary care and diligence should have left him with, after treating it, then the burden would be on the plaintiff, in order to sustain the verdict in this case, to show by the evidence that this result was brought about through lack of skill on the part of the physician, or through some wrongful or negligent act of omission or commission on his part. Neither of these conditions should be supported merely by theory, conjecture or inference, but they should be based on tangible, substantial evidence which the court and the jury may grasp and understand.

The plaintiff asked for $1,000 damages. He obtained a verdict for $500. But with all of the evidence before it on which the plaintiff could possibly predicate the hope of recovery, and there being in the court's opinion a total want and absence of the necessary elements to entitle him to recover, the court remanded the case with instructions to dismiss it.

Death from Erysipelas Following Injury is Attributable to the Latter

The Supreme Court of Montana says, on the second appearance before it of the case of McAuley vs. Casualty Company of America (102 Pac. R. 586), that it had a different record before it from what it had the first time. According to the latter, the court was clearly justified in concluding that a person could become ill from erysipelas in some manner other than by inoculation from an outside germ, through an abrasion of the skin. But all of the testimony on the second appeal showed that a person can contract erysipelas in but one way, namely the introduction of the germ of the disease through an abrasion of the skin. The only logical conclusion was therefore that Mrs. McAuley died from erysipelas—which the physicians said at the trial was a form of blood poisoning—caused by the germs of that disease entering her system through an abrasion of the skin of her leg, which she suffered in alighting from a street car.

It was contended by the casualty company, however, that this was not sufficient to fix a liability on it under its contract, for the reason that the disease germs might have been communicated to the hurt, not at the time of the accident, but from the hands of her husband, or from bandages or liniments which were immediately thereafter used and applied. But the court is of the opinion that this contention could not be sustained. These contracts of insurance, like all others, must be construed with a view to carrying out the intention of the parties. The manifest intention of these parties was that, if Mrs. McAuley was injured while riding as a passenger on a street car, the plaintiff beneficiary should be indemnified, to a certain extent, for his loss.

That the disease germs were communicated to Mrs. McAuley's leg from the hands of her husband, or from the bandages or liniment, was mere conjecture; there was no word of testimony on the subject. The jury found that she injured her leg at the time and place in question, and the proof showed that erysipelas manifested itself within the usual time. If a man not learned in the medical profession—one of the neighbors, for instance—were asked what caused Mrs. McAuley's death, he would undoubtedly reply that she scratched her leg getting off a street car, and that blood poisoning set in, from which she died. This is the way people generally understand these matters; and why should the courts adopt any other or different method of looking at the ordinary affairs of life? The injury and the erysipelas and the death were proven facts in the case. If Mrs. McAuley had not injured her leg in alighting from the car, there would have been no occasion to apply bandages or liniment, and the probabilities were she would still be alive. The defendant company induced the plaintiff to insure the life of his wife against accidental death; he paid the premium, and she thereafter died from the effects of an accidental injury. The court has no hesitancy in agreeing with the jury that the injury to her leg was the proximate cause of her death, and affirms a judgment for the plaintiff.

Current Medical Literature

1 Parasitism and Natural Selection. R. G. Eccles, Brooklyn.
2 *Acetone Treatment of Inoperable Carcinoma. D. W. Tovey, New York.
3 *Differential Diagnosis Between Certain Forms of Tertian Malaria and Enterogenic Intoxication. H. A. Houghton, Bayside, L. I.
4 *[illegible] A Symptom. J. N. LeConte, Altanta, Ga.
5 [illegible] M. Hellman, New York.
6 *[illegible] Antidiphtheritic Serum. F. M. Fernandez, Havana, Cuba.

2. Acetone Treatment of Inoperable Carcinoma.—Tovey reports eight cases of inoperable carcinoma treated with acetone as first used by Gellhorn. The patients had passed beyond the reach of any radical operation and in some cases the cancer had consumed the greater part of the cervix and vagina. The treatment, in a simple and harmless way, has given these patients a period of comparative ease and comfort. Tovey says that the treatment is of value only in inoperable cases, and does not give a permanent cure, but ameliorates the chief symptoms and makes the life of the patient endurable. The terrible odor, discharge, and hemorrhages are all relieved, and when they return the treatment can be given again without harm. The hemorrhages, septic absorption, and odor are all stopped.

3. Tertian Malaria and Enterogenic Intoxication.—According to Houghton many so-called cases of malaria of indefinite type are in reality cases of intestinal intoxication from non-digestion of foods, or the action of bacteria on digested but unassimilated foods.

4. Spastic Constipation.—According to LeConte, spastic constipation depends on a spastic contraction of the longitudinal and circular fibers of the intestinal wall, caused by inflammation or irritation. It is generally found in nervous, high-strung persons, especially women. The symptoms are attacks of sharp pain along the colon or radiating from the umbilicus, especially before the expulsion of gas or feces, dull aching pain in the intervals, and small scybalous or flattened stools, passed in two or three stools each day with much pain. Laxatives give much pain and act in large doses. Mucus in considerable quantity may be passed. Harsh, irritating foods, such as are used in the atonic variety, are harmful here. The diet should be bland and should consist of materials that can all be passed through a fine sieve. The condition is associated with mucous colitis in many cases.

6. Non-Specific Use of Antidiphtheritic Serum.—Fernandez advocates the use of antidiphtheritic serum in a number of non-diphtheritic diseases, in the nature of infections, either general or local. He has found it useful in suppurative keratitis of whatever origin, in infectious ulcers of the cornea, and penetrating wounds of the eye, in several respiratory affections, bronchopneumonia, and measles.

20 A Foreign Body in the Urethra. J. H. Dowd, Buffalo, N. Y.

19. **Influence of Hydrogen Peroxid on Hydrochloric Acid.**—Goodman has repeated the experiments of Petri in fifteen patients. Fifty cubic centimeters of a 3 per cent. solution of peroxid of hydrogen were made up to 300 c.c. with water, making approximately a 0.5 per cent. solution. An ordinary Ewald test meal was given and examined in the usual manner and was later followed by the peroxid test meal. No difficulty was experienced in getting the patient to take the latter, and no unpleasant sensations were complained of, with the exception of one patient, who said the "water had a fishy taste." There was a striking diminution in the quantity of free hydrochloric acid when a weak solution of hydrogen peroxid was substituted for tea in a test meal. Occasionally only a moderate decrease was observed, but in the majority of cases the decrease was astonishing, in some instances a total absence of free acid being noted. Not one of these six patients in whom the free acid was lacking, complained of any unpleasant sensations however. Only one patient, a neurasthenic and sullen youth, offered any opposition to the peroxid on account of the taste. Therapeutic application of the facts learned from these studies was made in a few instances. For use in the ward, a 0.5 per cent. hydrogen peroxid solution was made up in bulk and under the name of special water, was given to certain patients. The first patient to receive this water was suffering from headaches and gastric fermentation, and while under observation there developed an array of diurnally varying pains and symptoms. Another patient had the usual symptoms of hyperchlorhydria and suffered a great deal at night with burning sensation in the epigastrium. This was so intense that he was usually wakened out of a sound sleep by the pain. Hydrogen peroxid quickly relieved the distress, and although he stated that the special water made him sick for the time being, he became accustomed to it and drank no other water during his stay in the hospital. He was discharged cured, no other medicine being used except peroxid.

26. **Intestinal Perforation During Typhoid in Children.**—Jopson and Gittings studied the cases of perforation in typhoid occurring in children, and reported since 1903, with a view to confirming, if possible, the findings of Elsberg, and, at the same time, to consider briefly those points in the clinical course of typhoid in children that have a bearing on the diagnosis of perforation and to compare these with the symptoms commonly observed in adults. They collected from various sources 2,274 cases of typhoid in children in which perforation occurred thirty-five times (1.54 per cent). In collecting cases of perforation in children for study they fixed the usual age limit of fifteen years; they analyzed only cases in which operation was performed and perforation proved; they did not consider cases of peritonitis occurring without perforation, nor did they study cases of perforation of the appendix in which this lesion was manifestly due to a preexisting or coincident appendicitis not due to typhoid ulceration. Reported since the publication of Elsberg's paper in 1903, are 45 cases in subjects 15 years of age and younger, the exact age being given in 44. The youngest (4) were aged 5; 2 recovered, and 2 died. There were 3 patients aged 15 years, all of whom died. Of 21 patients under 10 years, 12 recovered, 9 died, a mortality of 43 per cent.; of 23 patients 10 years of age or over, 10 recovered and 13 died, a mortality of 56.5 per cent. In 31 cases the type of the disease previous to perforation was mentioned; 8 were mild, 15 were moderate, and 8 were very severe. Of the mild cases, 5 patients recovered, 3 died in cases of moderate severity, 8 patients recovered, 7 died. In the very severe cases 2 patients recovered and 6 died. The influence of the severity of the attack on the prognosis in cases of perforation as shown by these figures seems to be considerable. The child who is toxic and exhausted by prolonged hyperpyrexia is in poor condition to resist the additional complication and operative intervention. In 44 cases the time of perforation was definitely stated. The danger of perforation is greatest at the end of the second and during the third week. Nine patients were in relapse at the time of perforation; in another, a probable relapse, the duration of the disease was not stated, thus making ten cases in all. The date of the perforation ranged from the seventh to the fifteenth day of the relapse. Of these patients, 6 recovered and 4 died, a percentage of recoveries higher than that observed in unrelapsed cases. In 87.5 per cent. (21 out of 24 cases) pain was an initial symptom; in one case it was mentioned as not being initial; in two other cases it had been present during the illness to such an extent as to constitute a difficulty in diagnosis. In 89 per cent. (25 out of 28) the pain was severe. In the remaining 11 per cent. it was stated to be not severe. In 58.6 per cent. (17 out of 29) the pain was general in distribution. In 24.1 per cent. (7 out of 29) it was confined to the right side of the abdomen, especially the right iliac region. In 10 per cent. (3 out of 29) it was noted in the left side. In one case it was noted in the "upper" and once in the "lower" abdomen. In 10 out of 17 the pain was persistent, in 4 of which it continued to increase in severity. In 3 out of 17 it was intermittent in type; and in 4 it was distinctly stated to be "not persistent." Tenderness was noted as being present in 36 out of 45 cases. It was recorded as "general" in 15; prominent in the right iliac fossa in 9; confined to the "lower abdomen" in 2; and once to the hypogastrium. Rigidity is almost invariably present. It was noted as being absent in only 1 of 32 cases of the series in which full data were given, and in 1 it was absent early but appeared later. In 26 cases. vomiting was present 20 times and absent 6. Of the 20 cases, it occurred as an initial symptom in 4. Distention was noted as being present in 19 cases and absent in 11. Distention was present in only 50 per cent. of the patients who recovered and in 91 per cent. of the patients who died. In sixteen cases the normal area of liver dulness was diminished or almost obliterated; 5 times this was noted in early cases. Effusion. as indicated by movable dulness in one or both flanks, was noted as being present in 8

cases. In 12, information as to the temperature was entirely wanting. Of 33 cases there were 15 in which the temperature was depressed at some time subsequent to perforation, and in 11 of these it was specified that there was an immediate drop. In 6 there was no change. In 5 there was a rise at the time of, or shortly after perforation; and in 7 the temperature was fairly high. In 33 per cent. of the cases was it specifically stated that there was a pronounced initial drop in temperature; so that it is probably absent in more than half the cases occurring in childhood. A chill at the time of perforation was recorded in 6 cases. In 34 cases more or less satisfactory observations on the pulse rate were furnished. The majority of cases in children, as in adults, show an increase in the rapidity of the pulse rate; and in a considerable number, a weakening in the quality of the pulse may be looked for as an accompaniment of intestinal perforation. Shock was distinctly stated to be a marked symptom in 10 out of 45 cases, the most prominent alteration being in pulse and facies, and sometimes temperature—a rapid increase in the first; a pinched, pale, anxious expression in the second, and a fall in temperature, being the concomitant features. In 3 cases in which there was no shock the facies showed no change. The study of the data on respiration was unsatisfactory. Leucocytic counts were recorded in only 14 cases, in 6 of these repeated observations were made. They suggest that a falling count is unfavorable, while a high count or a rapidly rising count is of better prognostic significance.

The important diagnostic symptoms which are shown by a study of these cases are: pain, tenderness, and rigidity, which in children, as in adults, are early in their development and fairly constant in appearance. Next in importance, because less frequent, but of significance when present, are a drop in temperature, a rise in the pulse rate, and some degree of shock, often preceded or accompanied by vomiting, with perhaps a preceding or accompanying chill. A wave of leucocytosis will sometimes be recorded, and is at least as significant, if not more so, than in adults. Distention and obliteration or diminution of liver dulness are of little value in making the diagnosis in children, while effusion is mainly of value in confirming it. Other points are an absence of abdominal respiration, inhibition of peristalsis, and possibly a rise of blood-pressure, hitherto unstudied, in early life. The accident of perforation may be simulated in children, as in adults, by a number of other conditions.

28. Bacterial Content of Feces.—According to the authors, regulations of diet, together with the evacuation of the bowels, is the most effectual method that they have at hand of reducing the excessively high bacterial content of the intestine. Betanaphthol and bismuth salicylate appear to be the most effectual intestinal antiseptic drugs in normal individuals, while the aspirin and ichthalbin effect slight reduction, and salol gives no results whatever. The results produced by means of intestinal antiseptics in patients suffering with gastrointestinal disturbances, do not seem to be marked, whereas the best results are obtained by regulation of diet.

30. Cervical Rib.—The salient points in the case presented by Goodhart are: 1. Onset of symptoms at an unusually early age (7 years). 2. Severity of symptoms, which are practically limited to the nervous system. 3. Hypesthesia in the region supplied by the inner cord of the brachial plexus (ulnar distribution). 4. Progressive atrophy of the small muscles of the hand, including the thenar and hypothenar eminences. 5. Cervico-dorsal scoliosis. 6. Stationary character of the symptoms referable to the cervical rib, in the absence of surgical intervention. 7. Demonstration of the exact location of the roots of the brachial plexus in their relation to the supernumerary rib on the left side; digital pressure on each producing numbness and tingling in corresponding area of arm. 8. Diminution in size of the third normal rib on the left side, well-shown in the radiogram. 9. Beginning symptoms due to pressure on the opposite side. 10. Surgical removal of both cervical ribs.

33. Cardiac Hydrothorax.—The explanation which Fetterolf and Landis offer to account for these effusions that accompany heart disease is as follows: The fluid comes not from the parietal, but from the visceral pleura, and the outpouring is caused, so far as the pressure factor is concerned, by dilated portions of the heart pressing on and partly occluding the pulmonary veins. Two sets of blood-vessels enter the lungs, the bronchial arteries and the pulmonary arteries. The former are nutritional in function and are derived from the aorta or from the first aortic intercostal. They enter the hilum of the lung and follow the posterior surface of the bronchi, some of their terminal branches reaching and supplying the pleura. The pulmonary arteries, in addition to carrying venous blood to the lungs, send twigs to the pleura. In this membrane there is a capillary anastomosis between the terminal branches of the bronchial and pulmonary arteries, on the one hand, and the venous radicles which are tributary not to the bronchial but to the pulmonary veins, on the other. It is evident, therefore, that the venous blood from the visceral pleura is poured into the pulmonary veins, and, as a corollary, that any obstruction to the flow through this vein, if of sufficient power and duration, and if accompanied by whatever condition of the blood essential to transudation, would produce leakage through the visceral pleura into the pleural sac. Points in favor of the theory are that it explains equally well right-sided, left-sided and bilateral collections of fluid, and also accounts for certain intrapulmonary conditions found clinically and post-mortem in association with hydrothorax.

35. Abstracted in The Journal, June 5, 1909, p. 1875.

36. Cerebral Tumor.—The patient, whose case is reported by Rudolf and Mackenzie, for the greater part of her life had suffered from severe headaches, with some aphasia during the paroxysms. At the menopause the headaches rather lessened in acuteness, but the aphasia tended to last slightly, so that she would hesitate in speech and occasionally use the wrong words, both in speaking and in writing. Next she got an attack of what seemed like acute cerebral compression without localizing symptoms. This passed off, and she was as well as before for nearly ten weeks. Then the compression recurred, and again passed off, but recurred at intervals of a month, until the fifth proved fatal. Between the attacks she would seem nearly well, and on the day before the fatal one, spoke unusually well, and walked downstairs. The case during life seemed to be probably one of some sort of cyst, which periodically filled and after producing almost fatal compression emptied itself in some way. After the post-mortem, on stripping the dura from the cerebrum, it was found to be adherent over a large tumor mass which lay on and in the left cerebral hemisphere. There were a few small flat white tumor nodules on the inner side of the posterior portion of the dura over the left hemisphere and falx cerebri. A very large tumor was situated between the tentorium and the occipital lobe on the left side; this was attached firmly to the tentorium and was easily lifted away from the brain substance. There was considerable edema of the pia-arachnoid; the vessels of the left side were markedly congested and the convolutions were flattened. There was some dilatation of the lateral ventricles. The histologic characters of these tumors seemed to point without doubt to their being endotheliomata arising from the dura. The large soft tumor was of the ordinary cellular type of endothelioma; the large hard tumor and the small metastatic nodules in the neighborhood would fall into the class of so-called fibroendotheliomata.

40. Sleep Paralysis of Ulnar Nerve.—Gordon says that it is the traction or over-extension of the arm but not a prolonged postoperative lying position that is apt to produce an ulnar paralysis. If the latter were the real factor, ulnar palsies would be encountered very frequently, which is of course not the case. The ulnar palsy under the circumstances is probably the result of stretching of the nerve in its upper portion near the axilla. In sleep a similar phenomenon may be observed when an individual sleeps with the arms elevated, abducted, and behind the head. If the sleep lasts a long time the over-extension of the arm, and consequently of the nerve, is sufficient to interfere with the function of the nerve. Whatever the mechanism of ulnar neuritis in such circumstances may be, ulnar neuritis occurring during sleep is an infrequent phenomenon. As to the nature of the affection, all that can be said is: the normal function of the nerve has been interrupted; the over-extension of the nerve has brought on some molecular displacement which was sufficient to interfere with the proper conduction of stimuli through that nerve in a centripetal or centrifugal direction. Over-extension of a nerve is apt to tear its fibrils and its blood-vessels, and thus produce hemorrhages and inflammation. That an inflammatory state is not present is evident from total absence of pain at any stage of the disease and from the rapid improvement that follows treatment. This consists only of daily massage and of strict precautions against over-extension of the limb not only at night but also during the day.

49. **Rapid Method of Staining Trachoma Bodies.**—Verhoeff uses Wright's well-known modification of Leishman's stain with satisfactory results. The stain is applied in exactly the same manner as in the staining of the blood films. The specimen is conveniently obtained by scraping the cocainized conjunctiva with one edge of a cover glass instead of a knife, and by making use of the tears as a diluent instead of a salt solution as generally advised. If desired, the cover glass may be previously sterilized by flaming it. The tears and scrapings collected along the edge of the cover glass are then gently spread over the surface of another cover glass and allowed to dry in the air. The preparation is then flooded with the staining fluid which is allowed to act one minute. Distilled water is then added, about 8 drops, until a slight scum is formed on the surface of the mixture, which is allowed to remain three or four minutes. The preparation is then differentiated by washing off the staining mixture with distilled water and allowing the water to act about one minute. The differentiation may be followed by placing the cover glass film side up on a slide and watching the process under a low power of the microscope. The preparation is then quickly dried with fine filter paper and mounted in balsam.

50. **A New Law.**—This new law, discovered by Rhoads, is: The angle of refraction is the law of the perspective. All parallel lines are seen to approach each other at a one-minute angle. This angle controls all vanishing points, and all lines and planes; in fact, the size of all objects and the angle of all lines, whether large or small, broken, crooked, curved or straight. And, moreover, it matters not whether they are viewed downward from a balloon, upward from a coal mine, or outward from an observer at any conceivable incline. The horizon has nothing whatever to do with the vanishing of any lines or objects, unless they happen to be nine feet apart when they leave the observer. The angle within which the human eye cannot see is conceded to be one minute—the average may be a little less, not greater—therefore, the eye separating two cobwebs at twelve inches from it would place them at 3/1000 of an inch apart. At ten feet from the eye the angle would be 30/1000 of an inch wide. At three-quarters of a mile the angle would be twelve inches apart, while at three and a half miles it will be separated five feet two inches, which is just wide enough to admit a trolley track. This angle continued to the horizon would gap about nine feet. Prolong this angle over the edge of the horizon to the half-risen moon and objects would have to be seventy miles apart on the face of the moon to be visible to the unaided eye, and continuing this angle on to the sun, spots on the disc of the sun, viewed through a smoked glass, by the naked eye, must be over 27,000 miles in extent to come within, or rather without this angle, to be seen by the human eye. To project these lines on to the nearest measured star, which requires three years for its light to reach us, and they would be wide open to the extent of 42,000,000,000 miles, and double stars would have to be placed at the extreme corners of this vast isosceles triangle, or they would be blended into a single star. Rhoads believes that each pair of parallel lines in perspective is an isosceles triangle, and the length of its sides is governed by the width of its base; especially is this true if they are less than nine feet apart when they meet between the observer and the horizon. If they are wider than nine feet they gap on the horizon.

Parallel lines four inches apart would come together at 1,320 feet, only on twenty-sixth of the distance to the horizon. Parallel lines one foot apart come together at three-quarters of a mile, less than one-sixth distance to the horizon, and parallel lines two feet apart come together at a mile and a half from the observer. While lines nine feet apart come together on the horizon, all lines wider than nine feet, if on a level plane, gap at the horizon, but if they go up a mountain side or off into the air they meet where the one-minute angle brings them together, *i. e.*, where the human eye can no longer separate them.

57. **Congenital Umbilical Hernia into Cord.**—In the case reported by Catchings the cord was greatly distended at its point of insertion into the abdomen forming a tumor about two and one-half inches in diameter, and about three and one-half inches long. One side or half of this tumor was opaque, while from the other side the contents could be partly determined through the hernial coverings, owing to the thinness of the layers. It was a case of congenital hernia into the cord. Manipulation to reduce the contents was of no avail. The hernia was reduced by operative means. The contents of the hernia were cecum and appendix, a portion of the ileum and some omentum, all firmly adhered to the opaque side of the tumor. The infant recovered.

If they are wider than nine feet they gap on the horizon.

Parallel lines four inches apart would come together at 1,320 feet, only on twenty-sixth of the distance to the horizon. Parallel lines one foot apart come together at three-quarters of a mile, less than one-sixth distance to the horizon, and parallel lines two feet apart come together at a mile and a half from the observer. While lines nine feet apart come together on the horizon, all lines wider than nine feet, if on a level plane, gap at the horizon, but if they go up a mountain side or off into the air they meet where the one-minute angle brings them together, *i. e.*, where the human eye can no longer separate them.

59 Hystero-Salpingo-Oöphorectomy Duplex for Fibroids. W. R. McKinley, Columbus.

57. **Congenital Umbilical Hernia into Cord.**—In the case reported by Catchings the cord was greatly distended at its point of insertion into the abdomen forming a tumor about two and one-half inches in diameter, and about three and one-half inches long. One side or half of this tumor was opaque, while from the other side the contents could be partly determined through the hernial coverings, owing to the thinness of the layers. It was a case of congenital hernia into the cord. Manipulation to reduce the contents was of no avail. The hernia was reduced by operative means. The contents of the hernia were cecum and appendix, a portion of the ileum and some omentum, all firmly adhered to the opaque side of the tumor. The infant recovered.

63 *General Anesthesia in 5,400 Patients. A. V. Wenger, Grand Rapids, Mich.
64 Appendicitis in Children. G. Van A. Brown, Detroit.

63. **General Anesthesia.**—Five thousand, four hundred anesthesias with no fatalities is the experience recorded by Wenger. He urges that patients be prepared more thoroughly than is the general rule. Eliminate, so far as possible, the moving of patients after partial or complete anesthesia. When ether or chloroform are the drugs to be administered, use the

open method, drop by drop, so that elimination may progress in a comparative ratio to absorption. Except when contraindicated, give morphin from 1/8 to 1/4 of a grain, and atropin from 1/200 to 1/100 of a grain, hypodermically, from 15 to 45 minutes before anesthesia is begun, for the purpose of reducing the amount of drug and controlling mucus secretion. Keep the mouth clear of the mucus that is secreted, which, when laden with ether or chloroform and swallowed, is the most frequent cause of postoperative vomiting. If this is well looked after the frequency of vomiting will be much reduced. Always have a hypodermic syringe charged with at least 1/20 grain of strychnin and 1/100 of a grain of digitalin, and whenever possible, a second hypodermic charged with atropin 1/75 of a grain at hand. When anesthetizing the center of attention should be the business in hand, not the operation. Give only enough attention to the operation to guide in the degree of anesthesia. Be careful and gentle with the eyes. Keep in mind the fact that pupilary reflex and conjunctival reflex from drug vapor are sufficient guides and that they are fully as accurate as the reflex obtained by the finger touching the conjunctiva or cornea. Begin all anesthesias with ether or chloroform slowly, carefully watching the color of the patient and the condition of the pulse, respiration and skin. If the patient is markedly cyanosed it will often be found that a change from ether to chloroform or *vice versa* will relieve the condition. In tedious operations the patients should receive an infusion of saline solution, from one-half to three pints, according to indication. Always examine urine, heart, lungs and mouth, and always ascertain that all clothing is loose about the patient's body and neck.

99. **Compression of Superior Mesenteric Artery.**—It is evident from the physiologic experiments performed by Longcope and McClintock that constriction and ligation of the superior mesenteric artery will bring about immediately a slight but definite rise in blood-pressure, which is sustained over a short period of time, and so far as can be learned it is not possible to produce this same result by compression of any other branch of the aorta below the diaphragm. Two explanations are offered. The superior mesenteric artery supplies a relatively large area of the body, and the effect of constriction may be analogous to that resulting from compression of the aorta at the diaphragm. By obstructing the vessels a considerable proportion of the peripheral circulation is cut out, the peripheral resistance is increased, and the pressure, therefore, rises. Another explanation is, however, possible. Following complete ligation of the vessel there is, of course, marked anemia of the entire small intestine. This sudden anemia may induce, through a reflex action, an elevation of blood-pressure.

112 *Use of Silver Wire in Opening the Kidney. E. K. Cullen and H. F. Derge, Baltimore.

112. **Silver Wire in Opening Kidney.**—In man and dog there are, as a rule, two main arterial trunks supplying the kidney, one passing to the anterior, the other to the posterior portion. While studying the tree-like branching of these arterial trunks, the thought occurred to Cullen and Derge: Could it be possible to open the kidney in such a manner as to avoid the two main trunks, and, at the same time, do as little damage as possible to the finer branches. Anatomically, the proper procedure in performing a nephrotomy would be to cut from within outward, and some blunt instrument which would push the vessels aside would probably give the most satisfactory results. In order to determine the feasibility of this supposition, a series of nephrotomies was performed on dogs, and the results obtained were very definite and gratifying. A No. 3 silver wire was used as the blunt instrument, and proved very satisfactory, its pliability and low tensile strength making it almost impossible to tear any of the larger branches, providing ordinary care was exercised in pulling the wire slowly outward. Two series of experiments were performed to

determine, first, whether the direction of the incision had any appreciable effect on the resulting hemorrhage; that is, whether the hemorrhage would be less if the knife were passed from the region of the kidney pelvis out through the cortex and capsule, than from the capsule into the pelvis; secondly, whether the hemorrhage would be lessened and more readily controlled if a silver wire were used in lieu of the knife in splitting the kidney from within outward. In the first series of experiments, in which the knife alone was used, all the incisions were made in a plane at right angles to the curved vertical axis of the kidney. Two incisions were made in each experiment, one by passing the knife from cortex to pelvis, and the other by transfixing the kidney in antero-posterior manner close to the pelvis, and bringing the knife out through the cortex. Both of these incisions were made at a level of about 2 cm. from either pole and carried through the center of the lobule situated between the central and upper or lower polar lobule. In each instance, irrespective of whether the incision from pelvis to cortex was placed near the upper or lower pole, the hemorrhage was appreciably less when the knife was directed from pelvis to cortex than from cortex to pelvis. In the second series of experiments, both the knife and silver wire were used, and the experiments divided into two separate groups:

In the first group, the knife was used in making the incision near one pole and the silver wire near the other pole. The silver wire was usually employed first. A No. 3 or No. 4 silver wire threaded on a Kousnietzoff-Cullen straight liver needle was passed transversely through the kidney at the upper level of the pelvis. The capsule was then nicked with a knife from the point of entrance of the wire around to the point of exit. This procedure was found necessary to avoid trouble—some bleeding from the tearing of the capsule. With the kidney firmly held in the hand of the assistant, the wire was readily brought out through the cortex by a gentle see-saw motion. On examination, the cut surfaces appeared almost as clean-cut as if the knife had been used. In several instances bleeding, which was only a slight venous ooze, was so slight that a mere approximation of the two surfaces checked all bleeding, and had it been possible to keep the surfaces pressed closely together the kidney could have been safely dropped back into position without a single suture being necessary.

120. **Care of Insane Epileptics.**—La Moure advocates the establishment of a separate state hospital for the care and treatment of the so-called insane epileptics and the transfer of all epileptics from other state hospitals to such state hospitals for epileptics. With such arrangement many of the difficulties existing at present will, he thinks, be obviated. Beyond constituting a sufficient population to establish a large institution devoted to the solution of these problems, it is further pointed out that if this class were removed from present surroundings the vacancies thus created would provide room for an equal number of a non-epileptic class, thus tending to relieve the over-crowding which now exists.

2. **Cancer Research.**—Ross and Macalister place on record some facts regarding a chemical substance which causes a remarkable train of events when it is absorbed by human lymphocytes in that it promotes, first, excitation of ameboid movement, then reproduction, and lastly, it causes death. These events are closely related to each other, and follow in quick succession under experimental conditions. More than a year ago they noted that there appears actually to exist in the body-fluids of persons suffering from carcinoma a substance which causes the first of these events in the chain—namely, the excitation of ameboid movements. A mixture of methylene blue and atropin excites ameboid movements in leucocytes. So does the blood of a cancer patient. The same mixture will cause lymphocytes to extrude flagella with a particle of chromatin at their ends; so will the plasma of a cancer patient. Ross and Macalister have shown that an extrusion of chromatin also appears to be a phenomenon which occurs in cancer cells, and that cancer cells appear to produce "something" which aggravates the disease. It is possible, they say, that this "something" is chromatin, and in support of this theory is the fact that an extract which probably contains chromatin or a derivative of it accelerates the action of the artificial auxetic. The deduction is that this chromatin thrown out by the cancer cells may be the element which, by affecting some other unknown substance, may promote a repetition of the changes which cause the three events in the chain to which they have referred.

open method, drop by drop, so that elimination may progress in a comparative ratio to absorption. Except when contraindicated, give morphin from 1/8 to 1/4 of a grain, and atropin from 1/200 to 1/100 of a grain, hypodermically, from 15 to 45 minutes before anesthesia is begun, for the purpose of reducing the amount of drug and controlling mucus secretion. 120. **Care of Insane Epileptics.**—La Moure advocates the establishment of a separate state hospital for the care and treatment of the so-called insane epileptics and the transfer of all epileptics from other state hospitals to such state hospitals for epileptics. With such arrangement many of the difficulties existing at present will, he thinks, be obviated. Beyond constituting a sufficient population to establish a large institution devoted to the solution of these problems, it is further pointed out that if this class were removed from present surroundings the vacancies thus created would provide room for an equal number of a non-epileptic class, thus tending to relieve the over-crowding which now exists.

2. **Cancer Research.**—Ross and *Macalister* place on record some facts regarding a chemical substance which causes a remarkable train of events when it is absorbed by human lymphocytes in that it promotes, first, excitation of ameboid movement, then reproduction, and lastly, it causes death. These events are closely related to each other, and follow in quick succession under experimental conditions. More than a year ago they noted that there appears actually to exist in the body-fluids of persons suffering from *carcinoma* a substance which causes the first of these events in the chain—namely, the excitation of ameboid movements. A *mixture* of *methylene* blue and atropin excites ameboid movements in leucocytes. So does the blood of a cancer patient. The same mixture will cause lymphocytes to extrude flagella with a particle of chromatin at their ends; so will the plasma of a cancer patient. Ross and Macalister have shown that an extrusion of chromatin also appears to be a phenomeno [illegible] which occurs in cancer cells, and that cancer *cells appear* t[illegible] produce "something" which aggravates the disease. It is p[illegible] sible, they say, that this "something" is *chromatin,* and [illegible] support of this theory is the fact that an extract which p[illegible] ably contains chromatin or a derivative of it accelerates action of the *artificial* auxetic. The deduction is that chromatin thrown out by the cancer cells may be the [illegible] which, by affecting some other unknown *substance,* [illegible] *mote a repetition* of the changes which cause the three in the chain to which they have referred.

The promoter of the first of these events (exciter of ameboid movement) has already been described as existing in the blood of cancer patients, and to a greater extent in the juice of a growth. If chromatin, or a derivative of it, is the "something" which aggravates the disease, in order to produce a chain of events similar to that which has been observed in lymphocytes, it will have to aggravate the action of a substance resembling in effect that contained in the anilin dye which causes, first, reproduction and then death. It may also be noted that chromatin is a product of katabolism which, as has been suggested, may predispose to the disease in persons over the age of 40.

Experimentally one can induce mitoses in lymphocytes and these cells present characteristics resembling in many ways those appertaining to cancer cells. Cancer cells frequently show the first (heterotype) mitotic phase; but whether the mitoses induced in lymphocytes are of the first gametic variety remains to be proved. The research which Ross and Macalister have conducted has shown that the actual phenomena of mitosis in human lymphocytes can now be demonstrated. The remarkable differences between these cells and the other leucocytes are now apparent. Lymphocytes respond to the auxetic and endeavor to reproduce themselves, whereas leucocytes do not. The cytoplasmic (Altmann's) granules of leucocytes can be stained without harm to the lives of the cells. The nuclear granules of the lymphocytes, on the other hand, are composed of chromatin, and somatic death occurs when they stain. The fact that the nucleoli of lymphocytes form the centrosomes is also interesting, but not unique, from a cytologic point of view.

3. **Antitryptic Index and Malignant Disease.**—By the antitryptic index is meant the power of inhibiting tryptic digestion possessed by any given serum, compared with such inhibitory power possessed by a normal standard serum; or, in other words, the ratio of the powers possessed by different serums for neutralizing tryptic ferments. Bayly observed that most processes involving cell destruction, whether bacterial, mechanical, or cytolytic, produce a raising of the antitryptic index. The phenomenon, therefore, can be in no way regarded as specific, but this lack of specificity, though it narrows the scope of the reaction, still leaves an ample margin where its utility as an aid to diagnosis in malignant disease is clearly shown. It has been observed that the serum of patients with gastric ulcer gives a nearly normal reaction, and a diagnosis between this condition and carcinoma of the stomach can therefore be facilitated by the antitryptic test. Of 30 cases of cancer studied by Bayly, 26 (86 per cent.) show a markedly raised index. Of the remaining 4 cases (10 per cent.) 3 show practically normal indices, and one shows a subnormal index. This case was a very advanced one.

If bacterial infection is present, this method at the moment cannot claim any great diagnostic value, but in the absence of such infection its great help in affording a diagnosis between malignant disease and gastric or intestinal ulcers, non-malignant strictures, aneurisms, or non-malignant conditions of the bladder (such as stone), pelvic conditions in the female, is apparent. The negative evidence afforded by a normal antitryptic index is also of great value in excluding malignant disease.

4. **Serratus Magnus Infection in Breast Cancer.**—The observation of a number of cases of breast cancer which presented nodular recurrences about the lower half of the scar, led Henderson to believe that in certain instances such recurrences might be due to the almost invariable practice of leaving intact the serratus magnus muscle, perhaps already infected by outlying extensions of growth. If, he says, there are lymphatics in the pectoralis major which communicate at an angle with those in the pectoral fascia, the same arrangement is more than likely to hold good in the case of the serratus magnus, and it will be found in the future to be a routine necessity to remove the "exposed" portion of this muscle in the surgical treatment of those mammary cancers which overlie it.

6. **Rodent Ulcer Treated by Potassium Bichromate.**—The case under consideration was a woman of 82, with a history of having a "sore of the nose" for two years. On examination the condition was found to be typical of rodent ulcer. On account of the extent and position of the ulcer, it was thought impracticable to employ surgical means for its removal. A 10 per cent. aqueous solution of potassium bichromate was painted on the surface of the ulcer night and morning for a few days, until a marked inflammatory reaction in the surrounding tissues occurred, the ulcer being protected between times by a piece of lint retained in position by strips of sticking-plaster. The bichromate was then stopped, and a dressing of boracic ointment applied until the surrounding inflammation was allayed. The ulcer then appeared to be in a healthier condition, the floor having been partly destroyed and granulations becoming evident.

The process was repeated twice, potassium bichromate being painted on the ulcer night and morning as before, with a similar result, and being followed by the application of boracic-acid ointment. The effect of the potassium bichromate was the production of a sloughing of the unhealthy tissue over the whole floor, which extended also under the rolled edge of the ulcer. Healthy granulation was promoted, and after the completion of the third series of applications of the bichromate, the epithelium spread rapidly over the ulcer, which healed completely, leaving a somewhat irregularly pitted scar. From the beginning of the treatment till the ulcer was apparently cured occupied a period of three months.

7. **Omentopexy for Ascites Due to Liver Cirrhosis.**—Turner reports two cases: (1) Cure of ascites due to alcoholic cirrhosis; double radical cure of hernia subsequently; patient alive and well two years and nine months later. (2) Syphilitic cirrhosis; omentopexy; death.

19. **Hemorrhagic Diphtheria.**—According to Rolleston, cutaneous hemorrhages occurring during the early stages of diphtheria with or without hemorrhages from the mucous membranes and associated with other features of malignancy, occur in about 5 per cent. of all cases. The severity of the diphtheria attack is usually due to neglect of treatment at an early stage, but is sometimes due to precocious malignancy (syphilis). Hemorrhagic diphtheria is confined to children. It is not affected by the season, sex, or previous health. Reaction to antitoxin is delayed, and the usual sequelæ of serotherapy are much less frequent in hemorrhagic than in milder forms of diphtheria. The mortality of hemorrhagic diphtheria is over 80 per cent. All the patients who

recover suffer from extensive paralysis. Treatment should be large doses of antitoxin and frequent doses of adrenalin.

22. **Sudden Death.**—Sudden death, according to Brown, occurs at two epochs: (1) from birth up to 3 years of age; (2) from 30 onward. From 3 to 14 there is practically immunity, while from 14 to 30 very few cases occur. In the first period, females are affected more commonly than males, perhaps because male children tend to be bigger and stronger; while in the second period males are affected more commonly than females, because in adults the great cause of sudden death is vascular degeneration, to which males are notoriously more liable. Children under 3 are liable to die suddenly from apparently trivial illnesses. This liability is much the greatest during the first year. The post-mortem findings show a much greater variety of causes in children than in adults. Among these Brown found pulmonary collapse, suprarenal hemorrhage, and lymphatism. Among adults, the causes of sudden death are aortic regurgitation, which is the great valvular lesion producing sudden death, hemoptysis from advanced phthisis, vascular degeneration, which is the great cause of sudden death, especially premature degeneration—that is, while an active life is still being led; rupture or dilatation or an atheromatous artery is then much more likely to occur. Other causes are granular kidney without other obvious cause of death; atheroma of coronary artery; ruptured aneurism; pneumonia, cerebral hemorrhage; and persistent thymus.

33. **Internal Rotation.**—Paramore is of the opinion that the factors concerned in causing internal rotation of the head are: (1) the expulsive force from above; (2) the obstructing, central fixing force from below; (3) the shape of the pelvis; (4) the shape, size, consistence and position (flexion) of the fetal head.

Annals of Tropical Medicine and Parasitology, London

October

36 *Mechanism of Production of Hemoglobinuric Fever. J. O. W. Barratt and W. Yorke.

36. **Production of Hemoglobinuric Fever.**—This is the report of the blackwater fever expedition to Nyasaland of the Liverpool School of Tropical Medicine, 1907-1909. The report is very full and it is only possible to refer very briefly to some of the conclusions drawn by the investigators. The first point studied was the hemolysis of red blood cells by quinin and also by acid, alkali and urine. The authors found that quinin bihydrochlorid and quinin in the alkaloidal state produce hemolysis of red blood cells, as do also hydrochloric acid and sodium hydrate, and that the action of quinin in the alkaloidal state in producing hemolysis resembles a catalytic action. Hemoglobin breaks up at a monomolecular rate under the action of quinin in the alkaloidal state. These four hemolytic agents possess, in equimolecular concentration, nearly the same hemolytic power, quinin in the alkaloidal state being weaker, and quinin bihydrochlorid stronger than hydrochloric acid and sodium hydrate, which occupy an intermediate position. Owing to the toxicity of quinin its concentration in the blood cannot reach an amount sufficient to allow of its direct hemolytic action on red cells taking place during life. The red blood cells during blackwater fever are not hemolyzed by quinin bihydrochlorid more readily than in health. In the presence of urine, hemoglobin, whether contained in red blood cells or in solution, is broken up. In the former case this proceeds at a monomolecular rate, no hemoglobin being discharged from the red cells into the urine, until destruction is nearly complete.

In studying the mechanism of production of suppression of urine in blackwater fever, the authors found that during experimental hemoglobinuria dependent on hemoglobinemia, as also in the hemoglobinuria of blackwater fever, granular casts of varying size, sometimes very soft, sometimes firm and dense, often containing degenerated nuclei derived from the epithelium of the renal tubules, were met with in the urine. During suppression in blackwater fever the urine contained very large firm casts with exceedingly coarse granules, often surrounded externally by epithelioma derived from the ducts of Bertini, in which these casts were formed. The amber-colored urine passed during partial suppression contained a large amount of coagulable proteid. The average daily amount of urine passed during nine days of partial suppression was in one case 28 c.c., in another case 66 c.c. They conclude that suppression of urine in blackwater fever is of mechanical origin, due to a blocking of the renal tubules. During simple uncomplicated hemoglobinuria of blackwater fever the sole pathologic condition existing in the kidneys appeared to be the presence of brown granular material in the lumen of the renal tubules. Venereal disease does not appear to influence either the tendency to blackwater fever or its severity when present. The clinical histories of the 17 cases studied are given in full.

46 Robert-Houdin's Ophthalmologic Instruments. (Sur quelques instruments destinés à l'étude de la vision entoptique.) P. Yvon.
47 *Organotherapy in Addison's Disease. (Opothérapie surrénale dans la maladie d'Addison.) E. Boinet.

47. **Organotherapy in Addison's Disease.**—Boinet reports a case of well-defined Addison's disease in which the extreme languor, asthesia and emaciation indicated a rapidly fatal outcome, but under organotherapy the symptoms subsided and the patient, a man of 34, has been in good health during the ten years since. The gland substance was eaten fresh and a glycerin extract was injected two or three times a week. There are still traces of pigmentation, confirming, he thinks, the assumption of the nervous origin of this symptom. Béclère has reported a similar case of permanent recovery under organotherapy. The suprarenal treatment evidently acts by stimulating to hypertrophy the parts of the suprarenal capsules which are still intact, thus ensuring adequate functioning. Boinet cites five other cases that have been reported in France with marked improvement under organotherapy and adds three from his own experience, all the symptoms, except the pigmentation, showing great benefit from the suprarenal treatment. Two of these patients were women of 60 and 66, and the third was an omnibus conductor of 40 who was given treatment in the form of adrenalin by the mouth, 7 or 8 drops a day of the 1 to 1,000 solution. This was kept up for a month without signs of intolerance, and the patient regained his strength and resumed his work. In four other cases the suprarenal treatment failed to arrest the disturbances. One patient overdosed herself, with intolerance as the result and

...ous disturbances, the disease running its usual course. In the second case in this group a fibrocaseous tuberculous process terminated in the syndrome of acute suprarenal insufficiency. The patient was a mechanic of 33 with the classical syndrome of the disease, which was much ameliorated by injection of suprarenal extract for nearly a year. After a very fatiguing day he was given a subcutaneous injection of ½ mg. of adrenalin. This was followed by symptoms of acute suprarenal insufficiency, rapidly fatal. In the two other cases the rapidly fatal acute syndrome of suprarenal insufficiency followed soon after injection of one or two minute doses of adrenalin. In the condition which Sergent calls "Addisonism," that is, the Addison syndrome with pigmentation and capsular insufficiency resulting from sclerosis of the gland, as well as in the condition, without pigmentation, resulting from sclerous inflammation, the prognosis of superposed acute pulmonary affections is much graver than ordinary. This condition of Addisonism is more promising for organotherapy than the cases of fibrocaseous suprarenal tuberculosis. Suprarenal sclerosis is frequently encountered during or toward the end of pulmonary tuberculosis, while extensive fibrocaseous tuberculosis of the suprarenals is generally primary and is restricted to these glands. The secondary suprarenal process, causing Addisonism, in the course of tuberculosis of the lungs or intestines, is sometimes favorably influenced by ingestion of sheep suprarenal glands. In one such patient, the pigmentation has subsided and the symptomatic improvement has been marked. Sézary has recently compiled 17 cases of sclerous inflammation of the suprarenals presenting the syndrome of gradual suprarenal insufficiency with pigmentation—it is possible that the cases of recovery from Addison's disease under organotherapy all belong in this category and were not cases of true Addison's disease from primary and extensive tuberculosis of the suprarenal capsule.

Obstétrique, Paris

September, New Series II, No. 9, pp. 629-692

48 *Indications for Delivery by Rapid Dilatation of the Cervix. (L'accouchement par dilatation rapide du col.) P. Bar.
49 Historical Sketch of Maternities at Paris. C. Maygrier.
50 Twin Monster. (Monstre double derodyme tribrachie humain.) L. Tribondeau.

48. **Rapid Delivery.**—In this communication read at the international medical congress Bar compares the various methods for rapid delivery and the advantages according to the individual indications. He has used the Bossi dilator in 13 cases with no fatalities, but the cervix was lacerated in every case and the tear was very extensive in all but 3. In 20 cases in which he dilated the cervix with *his fingers*, laceration occurred in 30 per cent., and 2 of the women succumbed to hemorrhage. Bonnaire had also 16 per cent. of severe lacerations in 159 cases of digital dilatation. The inflatable bag has been applied by Bar for dilatation in 171 cases; the entire lower *segment was not torn* in any case and no fatal hemorrhage occurred, but slight lacerations were the rule. Lacerations in the cervix are liable to lead to *immediate* complications and by cicatric tissue growth to favor secondary infection of the cervi r. Except large multiparæ artificial rapid dilatati the ce unable to open the way entirely for d paratively insignificant lacerations caused instrument tear further as the chil being liable to extend far up into the ues.

60 Enrichment of Tubercle Bacilli by Antiformin. (Die Tuberkelbazillen-Anreicherung *mittels Antiformins.*) Hüne.
61 *Mutual Charges for Medical Services Between Physicians. (Gegenseitige ärztliche Honorierung.) J. Schwalbe.

55. **Treatment of Eczema.**—Scholtz expatiates on the importance of considering both the etiology and the pathologic anatomy in the treatment of eczema, including in the etiology external and internal, direct and indirect, primary and secondary *causes. Washing the part is injurious, not so much* from contact with the water as from the fact that the epithelium is deprived of the natural oil, its best protection. Toxic influences from within are an important factor, so that internal treatment is frequently necessary for a complete cure, *no external measures proving permanently successful* until the autointoxication is conquered. His experience confirms the service sometimes rendered by Roentgen treatment in chronic eczema.

58. **Restriction of Salt in Urinary Disturbances During Pregnancy.**—*In this communication from the late Professor Pfannenstiel's* clinic, Jaeger states that not only nephritis and eclampsia but also cystitis and pyelitis in pregnant women were not only attenuated but given a turn for the better by systematic withdrawal of salt accompanied by restriction of the *amount* of fluids ingested. These measures fail of course, like all others, in the severer cases, but they frequently prove effectual in banishing the edema of pregnancy nephritis and mitigating the other symptoms. The patient should abstain from all articles of food which contain large amounts of salt in the raw condition or require much salt to make them palatable; for this reason, meat and soups are excluded from the diet. *Milk contains too much fluid to be advisable as the* main reliance, and to many women it is repugnant. The diet is mainly sweetened, unsalted egg dishes, omelettes, etc. Unsalted butter is freely given, also rice cooked in milk, sago, baked potatoes, puddings and gruels with plenty of milk and sug vegetables without much salt, especially cauliflower, gr s, carrots and mushrooms, fruit and weak tea, lem l milk, *but no coffee. This menu allows sufficient* d the patients keep up their weight on it. This nfailingly to all patients with affections of the s. He gives several instances to show the this salt-poor diet and bed rest in severe s aid the fetus may be carried along to a If bed rest, salt-free diet, wet packs and ieve, *and the fundus of the eye* showed ture delivery was then induced, but ry in his experience, *as the restriction* ke of fluids almost invariably proved from 1,200 to 1,500 c.c. of fluids day. In conclusion he cites the case

of a primipara with nephritis in both kidneys, right staphylococcus pyelitis and mild cystitis, all of which subsided under the influence of the above measures.

59. **Rectal Saline Infusion in Treatment of Pyloric Spasm in Infants.**—Rosenhaupt calls attention to the specific action of salt solution in inhibiting the secretion of gastric juice. Recent research seems to indicate that the only rational and causal treatment of pyloric spasm is by checking the secretion of gastric juice. He has consequently been treating pyloric spasm in infants with rectal saline infusion and the results have convinced him that this is a specific means of treating this affection. It has failed only once in his experience, and in this case autopsy revealed an abnormally contracted stomach.

61. **Mutual Charges for Services Between Physicians.**—Schwalbe discusses the traditional custom that physicians treat their colleagues and their families without charging for their services. He shows how this custom was natural a century ago when the few medical men in a town or region were intimately acquainted with each other, but now conditions are entirely changed, and he urges that the custom be dropped, expatiating on its many drawbacks at present. Many medical men shrink from applying to a colleague for his gratuitous services when, if they were laymen, they would not hesitate to call on him. expecting to remunerate him according to the usual rates. The medical man is thus worse off than the layman. If he seeks to express his gratitude for services rendered by a gift, neither he nor the recipient feels satisfied. On the other hand, medical men sometimes have their services called into requisition by colleagues with scarcely a word of thanks. Schwalbe discusses the subject from all points of view and calls on the profession to cast away this antiquated custom, no longer corresponding to the present conditions. Fees for mutual medical service have nothing to do with professional honor, and whether medical men charge their colleagues for their services or not is not a question of medical ethics. He suggests that physicians who are intimate friends or professionally closely associated should not charge for mutual services. All others, those whom he does not know personally, the specialist is justified in charging for his services. It is every physician's right to pay for services rendered, medical or otherwise, and the consultant is under no obligation to refuse the fee. If he does not like to take a fee from his colleague, he can devote the money to some charitable purpose. The charge for the medical service should be, at most, in the medium grade of fees, not the highest. It is further to be expected that he will not insist rigorously on payment; the statement that the colleague is not able to pay the fee, or not until after a certain delay, should suffice to have the charge cancelled. In this way professional courtesy would be exercised in the ideal sense, but, as a rule, the principle should be maintained: *Beneficia nec obtrudantur nec exigantur*, "Favors should neither be thrust on one nor exacted."

65 Clinical and Bacteriologic Study of Actinomycosis. (Zur Kenntnis der menschlichen Aktinomykose.) H. Shiota.
66 The "Mesenterio-mesencolic Ligament" and its Connection with Ileus. A. Neumann.

63. **Implantation of the Ureters in the Intestine.**—Zesas gives a historical review of the subject and tabulates the details of 147 cases in which Maydl's technic was followed and of 24 in which the implantation was by the "axial" technic. The end-results so far as known are also given. In the 147 cases in which Maydl's operation for exstrophy of the bladder was done, only 20 of the patients were females. The operation proved successful in 103 cases; 44 patients died. including 16 from pyelonephritis. The outcome with the Maydl technic is compared with the results of operations by other technics, and the various advantages of each are discussed.

64. **Operative Treatment of Pseudarthrosis after Fracture.**—Creite gives a summary of the thirty cases in which operative measures were applied at Braun's clinic at Göttingen. All but one of the patients were males. Better results were obtained with the Dieffenbach technic than with resection and suture. This consists in driving into each stump a smooth round ivory peg, for which holes are drilled. The irritation of the foreign body stimulates production of callus, while the fixation from the pegs aids in restoration of normal conditions. The peg was driven across the bone and cut off where it emerged; when possible, it was driven so as to hold the stumps firmly together. The pegs were not removed afterward as Roentgen examination showed no reason for their removal. Consolidation was complete on an average in two months; the shortest interval was five and the longest twenty-eight weeks. A steel peg was used in one case, and no healing followed. In comparing the results of the different technics he admits that the ivory pegs were used only for the tibia while among the resected cases were some with the fracture in the arm or thigh, naturally more difficult to cure. All that he seeks to establish, however, is that for certain appropriate cases the ivory peg technic gives good results and can he relied on.

73 Influence of Carbonated and Oxygenated Baths on Viscosity of Blood. (Beeinflussung der Blutviskosität durch Kohlensäure- und Sauerstoffbäder.) E. Broking.

67. **Neuroses of Digestive Apparatus.**—Pick concludes his article by emphasizing the importance of causal treatment; many of the cases reported as psychogenic dyspepsia he is convinced were in reality enterogenic psychopathies. When the trouble is of psychogenic origin, suggestion, encouragement and training are in order, but when these fail and in all cases of primary gastric neuroses he advises local, medical, physical and dietetic measures. Alkalines and hydrochloric acid are sometimes effectual when their action fails to correspond to the chemical findings in the stomach content; alkalines may thus render useful service even when there is deficiency of gastric juice. Menthol has also proved valuable in treatment of nervous dyspepsia; the pain, vomiting, loss of appetite and flatulence may subside at once and permanently. He has found the menthol most effectual combined with an alkaline. Local application of heat is useful in the cases with hyperesthesia and hypersecretion; cold is generally not tolerated. In differentiating a nervous stomach trouble, the intolerance for drinking water often suggests the clue; with gastric ulcer solid foods cause greater disturbance.

70. **Ascending Infection of the Urinary Passages.**—Nohl calls attention to the possibility of ascending infection from even the slightest vulvitis, and the frequency of cystitis and pyelitis as the source of certain febrile affections of obscure origin in girls. The vulva may be apparently sound but some minute process may maintain the infection and entail recurring ascending infection of the urinary apparatus above, such as he has encountered in his practice.

80 Torsion of the Stomach. (Volvulus ventriculi und die Achsendrehung des Magens.) A. Payer.

76. **Acromegaly.**—Exner publishes his research on the 3 cases of malignant hypophysis tumors removed by Hochenegg,

nervous disturbances, the disease running its usual course. In the second case in this group a fibrocaseous tuberculous process terminated in the syndrome of acute suprarenal insufficiency. The patient was a mechanic of 35 with the classical syndrome of the disease, which was much ameliorated by injection of suprarenal extract for nearly a year. After a very fatiguing day he was given a subcutaneous injection of 1/3 mg. of adrenalin. This was followed by symptoms of acute suprarenal insufficiency, rapidly fatal. In the two other cases the rapidly fatal acute syndrome of suprarenal insufficiency followed soon after injection of one or two minute doses of adrenalin. In the condition which Boinet calls "Addisonism," that is, the Addison syndrome with pigmentation and capsular insufficiency resulting from sclerosis of the gland, as well as in the condition, without pigmentation, resulting from sclerous inflammation, the prognosis of superposed acute pulmonary affections is much graver than ordinary. This condition of Addisonism is more promising for organotherapy than the cases of fibrocaseous suprarenal tuberculosis. Suprarenal sclerosis is frequently encountered during or toward the end of pulmonary tuberculosis, while extensive fibrocaseous tuberculosis of the suprarenals is generally primary and is restricted to these glands. The secondary suprarenal process, causing Addisonism, in the course of tuberculosis of the lungs or intestines, is sometimes favorably influenced by ingestion of sheep suprarenal glands. In one such patient, the pigmentation has subsided and the symptomatic improvement has been marked. Sézary has recently compiled 17 cases of sclerous inflammation of the suprarenals presenting the syndrome of gradual suprarenal insufficiency with pigmentation—it is possible that the cases of recovery from Addison's disease under organotherapy all belong in this category and were not cases of true Addison's disease from primary and extensive tuberculosis of the suprarenal capsule.

48 *Indications for Delivery by Rapid Dilatation of the Cervix. (L'accouchement par dilatation rapide du col.) P. Bar.
49 Historical Sketch of Maternities at Paris. C. Maygrier.
50 Twin Monster. (Monstre double derodyme tribrachie humain.) L. Tribondeau.

48. **Rapid Delivery.**—In this communication read at the international medical congress Bar compares the various methods for rapid delivery and the advantages according to the individual indications. He has used the Bossi dilator in 13 cases with no fatalities, but the cervix was lacerated in every case and the tear was very extensive in all but 3. In 20 cases in which he dilated the cervix with his fingers, laceration occurred in 30 per cent., and 2 of the women succumbed to hemorrhage. Bonnaire had also 16 per cent. of severe lacerations in 159 cases of digital dilatation. The inflatable bag has been applied by Bar for dilatation in 171 cases; the entire lower segment was not torn in any case and no fatal hemorrhage occurred, but slight lacerations were the rule. Lacerations in the cervix are liable to lead to immediate complications and by cicatricial tissue growth to favor secondary infection of the cervix later. Except in large multiparæ artificial rapid dilatation of the cervix is unable to open the way entirely for delivery and the comparatively insignificant lacerations caused by the fingers, bag or instrument tear further as the child is born, the laceration being liable to extend far up into the cervix and environing tissues.

54 *Flap Method of Suturing Blood-Vessels. (Nouveau procédé de sutures artérielle et veineuse.) A. Pirovano.

52. **Walking Casts for Fracture of the Tibia or Ankle.**—A number of the 29 patients whose cases are reported were reexamined recently and the findings confirmed the good results of treatment with a cast which allows the patient to use the limb in walking from the first. There is no pain, edema, atrophy of muscles or stiffness of joints with these walking casts, as when the limb is immobilized. In the cases reported the healing was complete in a short time, the patients leaving the hospital cured by the fortieth or sixtieth day, with good functional use of the leg. The technic for making the casts is illustrated.

54. **Flap Method of Suturing Blood-Vessels.**—The stumps of the vessel are cut square across and then slit on each side for about a quarter of an inch. The two stumps are then approximated, the flaps spreading apart as the stumps are pressed together until the farther end of the slits on each stump are brought close together and sutured, the projecting flaps on each side being ligated at their base. Instead of a circular suture, there are thus only two linear sutures while the lumen of the vessel is not rendered any smaller.

61 *Mutual Charges for Medical Services Between Physicians. (Gegenseitige ärztliche Honorierung.) J. Schwalbe.

55. **Treatment of Eczema.**—Scholtz expatiates on the importance of considering both the etiology and the pathologic anatomy in the treatment of eczema, including in the etiology external and internal, direct and indirect, primary and secondary causes. Washing the part is injurious, not so much from contact with the water as from the fact that the epithelium is deprived of the natural oil, its best protection. Toxic influences from within are an important factor, so that internal treatment is frequently necessary for a complete cure, no external measures proving permanently successful until the autointoxication is conquered. His experience confirms the service sometimes rendered by Roentgen treatment in chronic eczema.

58. **Restriction of Salt in Urinary Disturbances During Pregnancy.**—In this communication from the late Professor Pfannenstiel's clinic, Jaeger states that not only nephritis and eclampsia but also cystitis and pyelitis in pregnant women were not only attenuated but given a turn for the better by systematic withdrawal of salt accompanied by restriction of the amount of fluids ingested. These measures fail of course, like all others, in the severer cases, but they frequently prove effectual in banishing the edema of pregnancy nephritis and mitigating the other symptoms. The patient should abstain from all articles of food which contain large amounts of salt in the raw condition or require much salt to make them palatable; for this reason, meat and soups are excluded from the diet. Milk contains too much fluid to be advisable as the main reliance, and to many women it is repugnant. The diet is mainly sweetened, unsalted egg dishes, omelettes, etc. Unsalted butter is freely given, also rice cooked in milk, sago, baked potatoes, puddings and gruels with plenty of milk and sugar, vegetables without much salt, especially cauliflower, green peas, carrots and mushrooms, fruit and weak tea, lemonade and milk, but no coffee. This menu allows sufficient variety and the patients keep up their weight on it. This diet is given unfailingly to all patients with affections of the urinary passages. He gives several instances to show the benefit derived from this salt-poor diet and bed rest in severe nephritis, as by its aid the fetus may be carried along to a viable condition. If bed rest, salt-free diet, wet packs and diuretics failed to relieve, and the fundus of the eye showed morbid changes, premature delivery was then induced, but this was seldom necessary in his experience, as the restriction of salt and of the intake of fluids almost invariably proved successful. Not more than from 1,200 to 1,500 c.c. of fluids are allowed during the day. In conclusion he cites the case

of a primipara with nephritis in both kidneys, right staphylococcus pyelitis and mild cystitis, all of which subsided under the influence of the above measures.

59. **Rectal Saline Infusion in Treatment of Pyloric Spasm in Infants.**—Rosenhaupt calls attention to the specific action of salt solution in inhibiting the secretion of gastric juice. Recent research seems to indicate that the only rational and causal treatment of pyloric spasm is by checking the secretion of gastric juice. He has consequently been treating pyloric spasm in infants with rectal saline infusion and the results have convinced him that this is a specific means of treating this affection. It has failed only once in his experience, and in this case autopsy revealed an abnormally contracted stomach.

61. **Mutual Charges for Services Between Physicians.**—Schwalbe discusses the traditional custom that physicians treat their colleagues and their families without charging for their services. He shows how this custom was natural a century ago when the few medical men in a town or region were intimately acquainted with each other, but now conditions are entirely changed, and he urges that the custom be dropped, expatiating on its many drawbacks at present. Many medical men shrink from applying to a colleague for his gratuitous services when, if they were laymen, they would not hesitate to call on him, expecting to remunerate him according to the usual rates. The medical man is thus worse off than the layman. If he seeks to express his gratitude for services rendered by a gift, neither he nor the recipient feels satisfied. On the other hand, medical men sometimes have their services called into requisition by colleagues with scarcely a word of thanks. Schwalbe discusses the subject from all points of view and calls on the profession to cast away this antiquated custom, no longer corresponding to the present conditions. Fees for mutual medical service have nothing to do with professional honor, and whether medical men charge their colleagues for their services or not is not a question of medical ethics. He suggests that physicians who are intimate friends or professionally closely associated should not charge for mutual services. All others, those whom he does not know personally, the specialist is justified in charging for his services. It is every physician's right to pay for services rendered, medical or otherwise, and the consultant is under no obligation to refuse the fee. If he does not like to take a fee from his colleague, he can devote the money to some charitable purpose. The charge for the medical service should be, at most, in the medium grade of fees, not the highest. It is further to be expected that he will not insist rigorously on payment; the statement that the colleague is not able to pay the fee, or not until after a certain delay, should suffice to have the charge cancelled. In this way professional courtesy would be exercised in the ideal sense, but, as a rule, the principle should be maintained: *Beneficia nec obtrudantur nec exigantur*, "Favors should neither be thrust on one nor exacted."

80 Torsion of the Stomach. (Volvulus ventriculi und die Achsendrehung des Magens.) A. Payer.

76. **Acromegaly.**—Exner publishes his research on the 3 cases of malignant hypophysis tumors removed by Hochenegg,

with retrogression of the acromegaly in the first 2, while in the third case the growth was too extensive to permit of complete removal. The close connection between the hypophysis and the functioning of the ovaries was evident in all; the thyroid gland increased in size after the operation in the first 2 cases. Exner points out features in the cases which show the close analogy between the conditions in pregnancy and in persons with deficient ovarian functioning on one hand and the conditions in acromegaly. In all there are changes in the hands and feet, abnormal growth of hair on the body, all of which return to normal on the conclusion of the pregnancy or removal of the hypophysis tumor. His research on the pathology and pathogenesis of acromegaly included transplantation of hypophyses in animals; it was followed by a gain in weight much beyond that of the controls. Study of the cases and results of experimental research have thrown light on a number of interesting points in regard to the mutual relations of individual organs.

77. **Functions of the Celiac Ganglion.**—In the case described, the retroperitoneal nerves had evidently been involved in a tumor which soldered the pancreas and rear wall of the pylorus together. The effect on the intestines was such as to simulate stenosis at several points, and experiments on animals confirmed the assumption that the celiac ganglion possesses fibers which have an inhibiting action on the movements of the intestines. When this ganglion is not functioning, the contractions of the intestines and peristalsis are much more intense and lasting than under normal conditions.

79. **Dilatation of Cecum as Independent Affection.**—Fischler has encountered 41 cases in which there seemed to be an isolated dilatation of the cecum, the syndrome suggesting chronic appendicitis in many respects, but it is evidently a morbid entity in itself. The appendix may or may not be involved in the process, but its removal does not effect a cure. The trouble is a muscular insufficiency of the cecum, the result of a localized catarrhal condition. The symptoms resemble those of dilatation of the stomach, the defective peristalsis, the sounds, the abnormal fermentations and gas formation, the catarrhal changes and the inability to pass the contents along. The affection is long in development and may persist indefinitely. He enumerates the various points differentiating the condition from Nothnagel's pseudoappendicitis, acute and chronic appendicitis, wandering kidney, affections of the adnexa and disturbances resulting from adhesions. In treatment, the aim should be to cure the chronic catarrh in the cecum. Albu demands a very exacting course of treatment for this, several weeks in bed, with tepid packs to the abdomen in case the disturbances are severe, vegetable food in the form of purées to keep the bowels regular, with oil, glycerin and soap enemas and a purgative twice a week, with belladonna suppositories three times a day and constant avoidance of physical exertion. But Fischler thinks that such a severe course of treatment is not required. The first thing is to exclude chronic appendicitis; this belongs to the surgeon. After the appendix has been removed, if this is necessary, the diet is regulated, reducing the amount of food as a whole, and inquiring to learn whether too much albumin, fat or carbohydrates is being taken in proportion to the total. Any excess of either should be stopped, and all substances liable to induce flatulence should be avoided for a time, dropping further from the diet any article of food which the patient has learned he cannot tolerate, milk in one case, beer in another, etc. Regular exercise is indispensable, especially that which calls the long muscles of the abdomen into play; when there is pain, it is best to avoid injudicious exertion. Massage is also useful, but the patient must be trained to apply it correctly, helping with light massage to push the contents of the cecum onward. The symptoms due to meteorism soon yield to appropriate massage, but applied ignorantly it is liable to increase the tendency to atony. Purgatives must be strictly avoided, as they aggravate the inflamed condition in the bowel. Oil and other enemas may be useful for a time, but they do not reach the seat of the trouble. The most important indication is to transform the intestinal flora, and this is best accomplished, he has found, by bismuth. He gives the subnitrate mixed with equal parts of magnesia usta to which a little pulverized rhubarb is added. A teaspoonful or less of this mixture is taken in water, after meals, three times a day, and benefit has always followed its persevering use. In case of much diarrhea he prefers bismuth salicylate as it is more constipating and has a stronger disinfecting action. He found bolus alba useful in 2 cases with much diarrhea and pain. Aside from these he gives no other drugs, but sometimes orders a wet pack at night over the region of the cecum. The patient soon learns to appreciate the benefit from the combined method of mixed but restricted diet, suitable regular exercise, massage and careful avoidance of allowing the abdomen to become chilled night or day, with occasional resort to the bismuth mixture as needed. He gives a detailed account of 3 typical cases out of his total of 41. An operation was required in 5. Two of the 3 cases reported were particularly instructive as the patients were physicians.

85. **The Cammidge Pancreas Reaction.**—Schumm and Hegler state that in many cases the response to the Cammidge test is merely a positive grape sugar test. They have simplified the Cammidge technic somewhat, and say that with their modification the test is more sensitive.

86. **Application of Cold to the Back of the Neck to Relieve Asthma.**—Marcuse confirms Muck's announcement in regard to the efficacy of the sudden application of a jet of cold water to the back of the neck as a means of controlling an attack of asthma. His experience has demonstrated that this is one of the most powerful means of acting on the respiration. The patient stoops over, and cold tap water is poured on the back of the neck from a pitcher holding over a gallon, held about two feet above; this is kept up for from half a minute to a minute and a half, or a strong jet of water is applied through a tube from the hydrant. He applies the water thus daily or two or three times a day, when the patient is being systematically treated for asthma, with or without preceding electric light baths. Muck advocates this measure as a means of relief in congested conditions in the nose, and Jurasz to arrest threatening espistaxis.

88 *Treatment of Stuttering. (Behandlung des Stotterns.) H. Gutzmann.
89 Action of Iodin. (Iodwirkung.) W. Heubner.
90 Importance of Supervising the Weight and Keeping the Appetite Good D [illegible] nt. (Bemerkungen über das Verhal [illegible] und die Diätetik während der Ilg. [illegible] isen.

88. **Treatment of Stuttering.**—Gutzmann is in charge of the university institute at Berlin for treatment of disturbances in speech, and his experience has convinced him of the extreme importance of careful study of the conditions in each individual case, not only the external and internal elements of the speech, but the character, temperament and secondary psychic phenomena, and after careful diagnosis, teaching the patient to imitate the processes of normal speech as he practices the elements in turn. To treat stuttering properly, he declares, the physician must be a good internist besides his special training in the nature and phenomena of stuttering. Among the points he has found particularly useful are training the patient to speak in a lower and monotonous tone, without stress on any syllables, the whole speech soft and gentle; when adult stutterers are particularly nervous he gives a little bromid preliminary to the exercises. A child who stutters does not get the training in speaking and expressing his

thoughts readily and in reading aloud which other children obtain, so that these children are backward in this respect after the stuttering is conquered. The main trouble in stuttering is in the defective use of the lips, tongue or throat, defective inspiration or expiration, even when the patient is speaking without stuttering. This is one of the reasons why psychotherapy fails—the underlying cause for the trouble has not been removed. Surgical treatment is effectual only in removing mechanical obstacles preliminary to the training of the organs to proper speech. The stutterer's dread and other secondary psychic phenomena subside spontaneously when he learns to control his speech. Gutzmann remarks in regard to quack advertisements that the "guarantee to cure" stuttering may afford a handle for prosecution of the quack as seeking to obtain money under false pretenses. Application of hypnosis to cure stuttering he regards as usually worse than the affection itself; he has frequently encountered cases in which hypnosis had been systematically applied by physicians over a long period without results. Dietetic and general tonic measures are always a powerful aid in the cure of stuttering.

91. Exclusive Milk Diet.—The indications for an exclusive milk diet have been considerably restricted of late years, especially in regard to nephritis and gastric ulcer. On the other hand, it is being recommended more than ever in the treatment of certain forms of heart disease, nervous prostration and in obesity. An exclusive milk diet has also been found useful in severe neuralgia. Hoffmann lauds it especially for this purpose, and His advocates avoidance of meat, at least.

92. Operative Treatment of Emphysema.—Strauch has had opportunity to examine three patients after the Freund operation had been performed, one both before and after the operative treatment for emphysema. The spirometer showed that comparatively little benefit had been derived from the operation; there was still an excessive amount of residual air, high total capacity and small vital capacity.

93. Blood and Urine in Leucemia After Roentgen Exposures.—The case of mixed cell leucemia reported is interesting, especially on account of the careful and prolonged study of the metabolism during Roentgen treatment and afterward on a diet free from nuclein, the research extending over six months. The findings are given in tabulated form, listed under thirty-two headings.

95. Improved Methods in Preparing the Food for the Sick.—Sternberg pleads again for the introduction into the household and the hospital of the methods of preparing the food practiced by French chefs. High art in culinary matters is characterized by extremely fine division of the substances, such as is possible only by grinding in a large mortar with heavy pestle and forcing through very fine sieves. The lack of these in the ordinary kitchen deprives the diet for the sick of its most important features. Ordinary strainers rest on the top of the vessel and it is impossible to apply much force. He advocates the drum hair sieve used by chefs, with meshes no larger than a fine needle. Considerable improvement is possible even with an ordinary kitchen sieve in the shape of a pan, if the sieve is turned upside down on the table so that force can be applied in putting the articles through it. He gives illustrations of chopped meat prepared for the ordinary ulcer diet and of the same meat as prepared by a chef, nearly half of the amount remaining on the strainer as connective tissue residue. This the chef uses for his soup stock, but in the hospitals or household it is all given to the ulcer patient in his chopped meat. It is important in putting the mass through the sieve to use a pestle for the purpose, rather than a spoon. He adds in conclusion that it is high time for dietetic therapy and technic to catch up with the progress in every other therapy and technic. The greater part of the work in high art cooking is in the preparation of the food before it is ready to cook.

103 Technic and Importance of the Wassermann Reaction. R. Müller.

100. Concussion of the Brain.—Ewald has been examining recently 45 patients treated since 1902 for concussion of the brain. He was surprised to find that only 11 had entirely recovered; the earning capacity in 23 was not materially impaired, although 12 patients had occasionally to leave work for a few minutes, hours or days on account of headache or vertigo. In 11 of the 45 cases extreme irritability had developed, but in one case it had subsided again. The memory was impaired in 9 cases. In 26 cases headache was complained of, continuous in a few. His experience shows that when the headache persists longer than six months permanent recovery seldom follows. In 12 other cases in which there was fracture of the base of the skull complete recovery was found in only 3 cases; the symptoms of vertigo, headache, irritability and restless sleep were more pronounced in this group. The 3 complete recoveries were in men who had had both fracture and concussion.

101. Technic for Evacuating Infectious Fluids.—Haberer gives an illustrated description of an apparatus which he has found extremely useful for evacuating the contents of the colon in ileus or of an ovarian cyst. Two tubes pass through the stopper into a large jar, one connected with an air pump, the other tube terminating in a trocar, fitting inside a small cylinder which presses firmly against the tissues as the trocar is introduced. The tissues are drawn up into this cylinder by the aspiration at the same time as the contents of the organ punctured are aspirated into the jar through the trocar. There is thus no danger of escape of the infectious fluid.

106 *Technic for Anesthesia by the Rectum. (Ueber Rektalnarkose.) F. Dumont.

104. The Viscosity of the Blood in Surgical Affections.—Müller has been examining the viscosity of the blood in 230 patients with surgical affections at König's clinic at Altona during the last two years. He has made 1,050 separate investigations; these have shown that the viscosity of the blood depends on the number and the hemoglobin content of the red corpuscles and on the albumin content of the serum. After an aseptic operation in which the peritoneum is opened the viscosity of the blood increases rapidly during the next day and then in the next four days gradually decreases to normal, and in the following two days drops considerably below normal, then gradually returns to normal by the end of the week. In case of acute inflammation the viscosity is abnormally high, but the gradual decline below normal forms the same characteristic curve as he shows by several examples. He calls this decline below normal the phase of exhaustion. The importance of these curves is shown in the fact that any focus of inflammation keeps the viscosity high, so that the rapid and regular postoperative decline is a sign of freedom from complications.

105. **Improved Technic for Vein Anesthesia.**—Bier's technic for this method of restricted anesthesia was described with an illustration in The Journal, May 1, 1909, page 1466. Momburg states that this technic has the disadvantage that the central constricting band gradually causes more and more discomfort to severe pain in the course of ten or fifteen minutes. This can be prevented by applying, after the anesthetic has been injected, a third constricting band just below the upper band and then removing the latter. The third band causes no discomfort as it is applied just within the margin of the anesthetized area. It can be applied over the minute incision made to expose the vein.

106. **General Anesthesia by the Rectum.**—Dumont protests that nothing but the fumes of ether should be allowed to pass into the rectum. His communication on rectal anesthesia was summarized in The Journal, Feb. 6, 1909, page 515. The unfavorable experiences that others have reported are due, he affirms, to neglect of the precautions which he advocated; chief among them is the interposition of a glass bulb between the jar of ether and the rectal tube. The ether has to traverse this bulb on its way to the rectum. It is brought into the bulb in a smaller, inner tube, the end curving downward inside the bulb, thus facilitating the dropping to the bottom of the bulb of any droplets that may condense from the fumes. In an operation of 80 minutes' duration 60 c.c. of condensed fluid accumulated in the bulb.

110 *Prophylaxis of Malaria. A. Graziani.

107. **Etiology of Nephritis.**—Maragliano declares that the present conceptions and classification of nephritis are erroneous; in nephritis the kidney is merely the exponent of a general morbid condition affecting the entire organism, defective oxidation processes, some profound modification in the cellular activity, with consequent accumulation of intermediate waste products. The nephritic kidney still retains its permeability; even in advanced degeneration there are always portions of the kidney left in good condition. These suffice for all purposes of elimination as a large part of the kidney tissue is a reserve supply in excess of what is required for ordinary functioning. The kidney is thus always permeable and it eliminates what it receives. The imperfect waste matters found in the urine in cases of nephritis do not testify to retention by the kidney, but merely to imperfect oxidation processes. Instead of testing for permeability and retention it is more logical, he asserts, to compare the total nitrogen and the ureic nitrogen as found in the urine and the blood. The problem is to decide the relations between the diseased kidney and the disturbances in the cellular processes. He adds that isolated brief periods of retention may occur from some nervous, inhibiting action or from obstructing of the tubules, but this is transient and elimination of an extra amount of waste follows. The disturbance in the cells results in production of some nephrolytic substance and the action of this on the kidneys, superposed on the general disturbances from the primary cause, produces the syndrome of nephritis. Both acute and chronic nephritis are curable if the primary morbid cause can be expelled. The kidney has a tendency to recuperate, and this change in the conception of nephritis puts an end, he declares, to the traditional fatalism in regard to the prognosis.

108. **Treatment of Nephritis.**—Calabrese protests against exaggeration and exclusiveness in dieting in nephritis; there is no need to exclude salt, he says, unless tests show that there is retention of chlorids. Unusual quantities of fluids need not be advised unless there seems to be a tendency to functional paralysis on the part of the kidneys. In this case water is better than drugs to stimulate kidney functioning unless the heart is weak and dilated, in which case the intake of fluids should be restricted. Venesection applied to the foot drains the congestion in the renal artery most effectually, but the main reliance is on measures to promote oxidations, and the elaboration of the albuminoid molecule by inhalation of oxygen and administration of iodids and alkalines. Organotherapy and serotherapy to date are still on trial. Surgical intervention is purely symptomatic and should not be considered until after failure of all medical means.

109. **Primary Splenomegaly.**—Micheli concludes his review of primary splenomegaly by stating that only primary tuberculous splenomegaly and Banti's disease, which he identifies with adults' splenic anemia, can be regarded as true primary splenomegaly. Bozzolo discusses treatment and relates his experience in 3 cases of Banti's disease in which splenectomy was done in 1900, 1902 and 1905 respectively. The patients were women between 29 and 45, and the cure has been complete to date, but in 3 other cases the patients did not survive the operation, and in 3 others it could not be concluded. The gravity of the operative traumatism, the multiplicity and toughness of the adhesions, the hemorrhagic diathesis and the lesser resistance of male patients, explain the difficulties and dangers of operative intervention in these cases. It seems to be always followed by gastrointestinal hemorrhage, pneumonia or fever, and should not be advised in all cases, especially not in advanced stages. A less difficult operation, possibly omentopexy, might answer the purpose. Tansini combined this with splenectomy in one successful case. In primary tuberculous splenomegaly, on the other hand, the patient can only gain by the splenectomy, even when the liver is involved in the process. Removal of the tuberculous spleen has given encouraging results to date in the cases on record. The liver lesions are arrested and retrogress.

110. **Prophylaxis of Malaria.**—Graziani has been studying the effect on the organism of long-continued administration of minute doses of quinin such as are advised as a prophylactic measure in endemic foci of malaria. The growth of young animals under the influence of minute doses of quinin for 100 days was compared with that of controls, the series including 24 rabbits and 30 guinea-pigs. The bactericidal and phagocytic power of the serum was tested for the malaria germ and the typhoid bacillus both in the animals and in clinical cases. The animals given the quinin (subcutaneous injection of 0.005 gm. per kilogram) lost weight or failed to take on weight in comparison with the controls. No influence could be detected on the bactericidal and phagocytic power of the serum, but the power of producing antitoxins seemed to be diminished, suggesting that prolonged administration of even these small doses of quinin might render the course of an infectious disease more serious and recovery more difficult. He cites in conclusion Serafini's remark that hygiene does not regard with approval any method of prophylaxis based on the introduction into the organism of any drug; it creates an abnormal, nonphysiologic condition, and is permissible only as a temporary expedient.

THE VALUE AND LIMITATIONS OF SALT-FREE DIET AND RESTRICTION OF FLUID IN NEPHRITIS *

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

Whatever one says under this title must be said with some caution and with a right reserved to change opinion with advance in knowledge. Although nearly one hundred years have passed since the question of the nature of the toxic constituents of the urine was first submitted to experimental inquiry, it cannot be regarded as yet settled. We can not to-day name all the poisonous constituents of the urine. I am not going into the literature of this subject in this paper, because it is too voluminous, in many points contradictory in its findings and unsatisfactory in the conclusions reached. The following points seem to be fairly well established:

1. Urea and uric acid are not important constituents of the urine so far as their toxicity is concerned. I mean to say that neither of these can be regarded as the active agent in the causation of those symptoms that result from failure to function on the part of the kidney.
2. About 85 per cent. of the toxicity of the urine is due to its inorganic constituents, the most toxic of which is potassium chlorid.
3. There are present in normal urine certain organic poisons, the nature of which has not yet been ascertained.
4. Although the inorganic constituents, notably potassium chlorid, are markedly poisonous, they can not be regarded as standing in a direct causal relation to that complex of symptoms which we designate as uremia. A small fraction of a grain of potassium chlorid, as I have frequently demonstrated, injected into a ventricle of the brain of an animal, may cause prompt death, but neither the symptoms nor the postmortem findings are those of uremia.

Of one thing I feel quite confident, and that is in withholding salts from our nephritics we are not withholding the direct cause of uremia. The best that we can hope for in the use of a salt-free diet is to protect the kidneys by decreasing to a certain extent their labor and thus conserving their capacity as organs of elimination. The inorganic salts, and certainly the chlorids of sodium and potassium, are not, singly or combined, the active and direct cause of uremia. Any inorganic salt above that needed in the processes of metabolism is without benefit to the body and increases unnecessarily the stress of work thrown on the kidneys, and, when these are already diseased, it is in accord with good sense to lighten their burdens so far as can be done without danger.

There are some reasons for suspecting that the inorganic salts of normal urine, carrying about 85 per cent. of the toxicity of this fluid, and the organic constituents, carrying the remaining 15 per cent. of toxicity, partly neutralize each other. At least it has been repeatedly found that the ash of urine is decidedly more toxic than the whole urine. This fact has been observed by Bouchard, Stadthagen and others. I have repeated this test several times with the urine of both herbivorous and carnivorous animals, also that of man, and have invariably found it true. It has been suggested that it is due to the conversion of the chlorid into a more poisonous carbonate on incineration, but I have been unable to find any evidence of carbonate in the ash which I have injected, and it has occurred to me that possibly there may be some neutralization between the inorganic and organic constituents. This is a problem that seems worthy of more extended study.

There is evidence that an absolutely ash-free diet may soon disturb the health of a normal individual. Taylor[1] has prepared such food and used it himself. He says:

> "The symptoms were those of lassitude until about the sixth day, when I noticed a great deal of cutaneous irritation and generalized muscular twitching with excitation of the reflexes. The equilibrium of the entire system became disturbed; I lost the power of sleep; the irritability was extreme. At this time the acetone complex appeared apparently suddenly. I therefore realized that I was near the danger point, stopped the experiment, resumed ordinary diet and within a few hours after the ingestion of alkalis, the symptoms disappeared entirely."

This experiment was repeated on two men by Goodall and Joslin,[2] who failed to induce the acidosis experienced by Taylor. This matter also needs further study. In all of these experiments the amount of sodium chlorid in the daily urine diminished to about 0.2 gm.

In dogs long-continued feeding of a salt-free diet materially reduces the acidity of the gastric juice. So far as I know, no experiments along this line have been made on man. It has been repeatedly shown, however, that it is difficult and probably impossible to reduce the amount of salt in the living tissues below a certain, fairly well-defined minimum. Life is no longer possible when this reduction passes this point. The molecules of living cells do not function when the content of inorganic salt falls below this minimum, which varies in different animals and in the different organs and tissues of the same animal. Notwithstanding all the excellent work that has been done on metabolism, we are hardly warranted in making more exact or positive statements on this subject. It is generally held that the chlorids of the urine are not in organic combination, but, as I have stated, it has been repeatedly found that the ash of urine is more toxic than the whole urine. Moreover, single inorganic salts may be more poisonous when injected intravenously than mixtures of several salts. There are, therefore, reasons for suspecting that the inorganic constituents of the urine are not only in part neutralized by the organic, but also in part by one another. The fallacies of Bouchard's method of determining the toxicity of the urine has been repeatedly pointed out, and his conclusions can not be accepted as final. Besides, it should be evident that poisoning due to the retention of normal constituents of the urine and uremia are two quite distinct and different things. Many years ago Rees reported a case in which there was only one kidney, and, this becoming blocked by a calculus, there resulted complete anuria. The man died, but not from uremia. Cases of prolonged suppression have been repeatedly observed and, although these may terminate fatally, death is not due to uremia. In uremia the poison results from a radical change in metabolism, and the active agent produced is not one of the normal constituents of the urine. It is possible that protein sensitization may give us more exact information concerning the nature of the poison elaborated in uremia. But the one point that I wish to emphasize in this paper is that poisoning from anuria and uremia are two distinct things, and, while the inorganic salts are the most poisonous constituents of the urine, their retention in the body can not be regarded as the cause of uremia—certainly not the direct cause.

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] Taylor: Tr. Assn. Am. Phys., 1907, p. 245.
[2] Goodall and Joslin: Tr. Assn. Am. Phys., 1908, p. 92.

In 1903 it was suggested by Widal that nephritic edema is due to chlorid retention, that with the disappearance of the edema the elimination of chlorid is increased, and that the proper treatment of the edema of nephritis should provide a diet that is largely salt-free. The reasoning in this statement seems to be good, but the experience of clinicians has not been so satisfactory as the earlier reports led us to expect. In Widal's first case the edema seemed to fluctuate directly with the amount of salt in the food and it was suggested that the milk diet, so long and favorably known in the treatment of nephritis, might owe its success largely to the fact that it contains only a small amount of sodium chlorid. Moreover, there is some clinical evidence that edema does increase the danger of uremia. At least uremic symptoms have been seen to disappear with the disappearance of edema and to return with the accumulation of fluid in the tissue. That there is a causal relation between edema and uremia does not, however, seem probable, because the latter is frequently seen in interstitial nephritis when the former is absent or but slightly developed. Edema in nephritis is due to diverse causes, and certainly not always to salt retention. In acute nephritis it seems to be due to the effect of the poisons on the walls of the vessels. In many cases of chronic nephritis, edema is due to circulatory disturbances and is best combated by agents directed to these causes. In amyloid nephritis it is again toxic. In a certain small percentage of cases of chronic parenchymatous nephritis the edema is apparently markedly influenced by the quantity of salt in the food, and it is in these that the best results are obtained by reduction of the salt in the food. Even in these the improvement is limited to the reduction of the edema. I do not deny that this is of sufficient advantage to be worth doing. It seems to me that the greatest good is to be secured by restricting salt in the food of those patients who may be called prenephritics. We frequently meet with patients of this kind. They are men and women past the prime of life who have been unduly energetic, often of good habits, with the exception of the tendency to overwork. The heart has been unduly taxed; they get out of breath easily; occasionally they grow dizzy. Blood-pressure is high. There may be a trace of albumin in the urine or the most careful and frequent examination may fail to show this abnormality. I am in the habit of advising patients of this class to have their food prepared without the addition of salt. I do this for the following reasons: 1. They can educate themselves to eat unsalted food. I am positive that we eat too much highly salted food. 2. With unsalted food they drink less. Vesicular fulness can be induced by water as well as by beer. 3. The kidneys are relieved of excessive work in eliminating excess of both salt and water. Otherwise I have never been satisfied that I have seen any benefit in any form of nephritis in denying the patient the satisfaction of his thirst.

Milk contains about 2 gm. of sodium chlorid per liter, and on an exclusive milk diet three liters per day supply the necessary calories for the average man. On such a diet the individual receives daily about 6 gm. of salt, and this seems to be all one needs in health or in disease. A mixed diet of unsalted meat, potatoes, bread, butter, fruit, sugar, cream or milk and coffee or tea of equal caloric value contains in the daily ration about 3 gm. of salt, and this may be increased by the addition of an equal amount if the taste is objectionable.

Time will not permit me to take up the interesting subject of the mechanism of nephritic edema, but I will call attention to a recent contribution to this subject by Bence,[3] who has shown that there is an increase in the volume of blood and edema appears in renal insufficiency even when there is no fluid taken into the alimentary canal; but, of course, both of these conditions are increased when much water is ingested. It seems only good sense, therefore, to limit the consumption of fluid in nephritis so far as possible without distress to the patient, but it should be understood that edema develops in experimental animals in which nephritis has been induced by the subcutaneous injection of uranium salts even when such animals are denied any fluid.

THE CAUSES OF HYPERTENSION IN NEPHRITIS *

JOHN H. MUSSER, M.D.
PHILADELPHIA

Of the causes of hypertension in nephritis we have no exact knowledge. The theories which have been elaborated are based mainly on deductions from clinical experience or to a slight extent on experiment. Neither the clinical experience nor the experimental evidence is at all conclusive; but each in its way points to an explanation through the action of some chemical substance influencing the circulatory system. What this substance is and how it acts we do not know.

Clinically we have the very important observation that hypertension and heart hypertrophy come in that group of renal diseases in which uremia is also prone to occur, while both fail in practically all other forms, as tuberculosis, pyonephrosis, hydronephrosis, cystic kidney and the kidney of acute sepsis. In other words, hypertension, like uremia, is an evidence of renal insufficiency. It is naturally suggested that the poison of uremia is identical with that causing hypertension, or, if different, is formed at the same time and due to the same causes; or possibly one is a derivative of the other as the result of some process of chemical disintegration. If the same poison, it is possible to conceive that in small amounts it affects the vasomotor apparatus (hypertension) and in large amounts exerts a toxic effect on the nervous system (uremia). Or, if two or more poisons are concerned, each may have special affinities.

---

[3] Bence: Ztschr. f. klin. Med., 1909, lxxvi, 69.

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In support of this chemical theory we have the frequent clinical experience that the degree of the uremic manifestations (headache, vomiting, unconsciousness) and the recovery from these have a close relation to the blood-pressure. Moreover, true uremia without hypertension seldom occurs.

In connection with this chemical theory or retention theory, the effect of diet also is suggestive. Experiments on patients with chronic nephritis have shown that rich protein diet increases tension and disturbs the general condition of the patient for the worse. Müller describes an individual in whom a change from milk and carbohydrate diet to rich meat diet caused pressure to rise from 140 to 190. Rich meat diet causes, in nephritics, headache, one of the earlest and most constant symptoms of uremia, and one which has a definite relation to hypertension.

All this probably means a retention of the products of nitrogenous metabolism, and possibly of that nitrogen which in the urinary partition is known as "rest" or undetermined nitrogen. The increase of these substances in the blood of that group of renal diseases in which uremia occurs suggests that not only may they be the cause of uremia, but that among them may also be the substances responsible for the increased tension. Aside from this theory, which attempts to explain clinical observation, we can at present add nothing to the view that hypertension is to be explained by retained products of metabolism.

Another view, which I think we can dismiss briefly, is that of the internal secretion of the kidney. This is based on Tigerstedt's observations that extracts of rabbit's kidneys contain a pressor substance, which substance Forlarini and Riva-Rocci consider may be increased in diseased kidneys. Little evidence has been brought forth to support this theory, and the most recent study, that of Pearce, was entirely negative in its results.

Another closely related theory is that which assumes a correlation between the kidney of chronic interstitial nephritis and the secretion of the adrenal. This theory was advanced by French investigators, led by Vaquez, three or four years ago. They describe a localized or diffuse hyperplasia of the adrenal accompanying chronic nephritis in those cases which do not run too rapid a course. This hyperplasia is considered as an indication of the hyperactivity of the functions of the gland; that is, essentially a condition of hyperadrenalism. Naturally the theory has a relation also to the arteriosclerosis associated so constantly with the interstitial type of nephritis. Although the correspondence between the renal lesion and the hyperplasia of the adrenalin is very suggestive and the occurrence not infrequent, there is some doubt as to the interpretation. Several German investigators, and in this country, Pearce, ascribe the anatomic changes in the adrenal, in part at least, to the influence of the local nutritional disturbances caused by local arteriosclerosis. As reports multiply, and the lesions are found in other conditions than "contracted" kidney, the importance of the observation diminishes.

Of interest in connection with the theory just described are the attempts to demonstrate adrenalin or adrenalin-like substances in the serum of nephritics. This work is based on Meltzer's observation that adrenalin causes dilatation of the pupil of the frog's eye. According to Ehrmann, the method is sufficiently delicate for the detection of adrenalin in dilution of 1 to 1,000,000. Clinically the method is associated with the names of Schur and Wiesel, who found that the serum of patients with chronic nephritis caused almost uniformly mydriasis of the enucleated frog's eye. The serum of normal individuals and of individuals suffering from other diseases failed to produce the same results. Several observers have confirmed these results, but there is some dispute as to whether or not the action is due to adrenalin. That it is, is denied by Schlayer, on the basis of his work with the "vessel-strip" method, which gives positive results with normal serums and no different results with nephritic serums. Be this as it may, no explanation of the presence of the mydriatic body is at hand unless it be that of the French investigators and that, we have seen, is hardly satisfactory. More evidence must accumulate before a definite opinion as to the value of these observations can be reached.

As is well known, the chief difficulty in explaining hypertension in chronic interstitial nephritis is the almost constant presence of arteriosclerosis. The absence of definite knowledge of the sequence of events makes the problem a complicated one. It is still a question whether the kidney injury is primary and leads to arteriosclerosis as the result of a hypertension of renal origin, or whether a poison first affects the blood-vessels, and the kidney secondarily through the disease of its own arteries. The latter view appears to be the one gaining adherents, but it is well to remember in this connection that many poisons may simultaneously affect the kidneys and the vascular system.

On this general subject some light has been thrown as the result of the study of renal diseases following infectious diseases, in which hypertension appears to be primary and the heart hypertrophy and arteriosclerosis secondary. The hypertension associated with the glomerulonephritis of scarlet fever is of peculiar interest. Usually one thinks of hypertension coming on gradually in the course of a chronic disease, but in scarlatinal nephritis it may develop very early (Mahomed and Müller); indeed, in the course of a few days. Here certainly heart hypertrophy or arteriosclerosis can be ruled out, for in scarlet fever four weeks at least are necessary for hypertrophy (Müller) and the scarlet fever age is not that of arteriosclerosis. For such an early hypertension the only explanation which can be offered is increased peripheral resistance—a contraction of arterial terminals—as the result of some chemical influence; but this brings us again to the theories discussed above, concerning which we could come to no definite conclusion.

The frequency of the association of glomerular lesions with hypertension is of considerable interest. Schmidt, working with Krehl's material, has emphasized this relation and A. Loeb holds that heart hypertrophy occurs only in those forms of nephritis in which the glomeruli are diseased and in large part impermeable. He points out that in the forms of nephritis with degenerative epithelial lesions only, hypertension does not occur; it is peculiar to scarlatinal nephritis and contracted kidney.

This is an important field for investigation: first, as to tension in various *forms of epithelial* lesions, especially those of the acute infectious diseases; and, second, a cooperation between the clinician and the pathologist as to the relation of hypertension to histologic changes, with special regard to the glomeruli.

Experiments definitely demonstrate that the high pressure associated with glomerular lesions can not be explained by the earlier theory of diminution of vascular territory in the kidney. Loeb offers the following hypothesis:

Since the renal activity varies directly with the blood-supply, lesions of the glomeruli would limit local vasodilatation. When the renal activity demands more than the local conditions allow, the stimulus goes beyond the kidney and there is exerted reflexly a splanchnic contraction which leads to an increased systemic tension and then an increased flow of blood through the glomeruli.

This explanation, hypothetical as it is, brings out very prominently the fact that hypertension, be its cause what it may, is essentially a conservative process having for its object the maximum functioning power of the kidney.

Passler and Heineke have attempted to explain the problem by reducing the kidney substance of animals by successive excisions. They found that after two-thirds to three-fourths of kidney was removed a certain proportion, about 25 per cent., of the animals developed a permanent increased tension with heart hypertrophy. In such animals it was also observed that arterial spasm with a further rise of pressure quickly followed certain stimuli which in normal animals would produce little effect.

They conclude that in the state of renal insufficiency so produced the heart hypertrophy is due to the increased work resulting from the tendency to arterial spasm and that this in turn is due to the effect of retained toxic substances.

So again we come back to the chemical theory of retention—all theories except that of vicarious adrenal secretion return to this point—but of the substances "retained" we know nothing. Herein is the problem of the "causes of hypertension in nephritis"—a problem to be solved only by the methods of chemistry and physiology directed by careful clinical observation.

P. C. Janeway (Prof. Soc. Exper. biol. and Med., 1909, vi, 108-109) has furnished a brief account of a study of the blood pressure in dogs with insufficient kidney substance. Instead of excising a portion of the kidneys he caused destruction by ligating some of the branches of the renal arteries. Also, instead of studying the pressure by direct measurements from the carotid, he modified the Riva-Rocci cuff so that the clinical method of taking blood pressure could be applied to the dog. Thus observation could be made from day to day with a limit of error of only 10 to 15 mm. Hg. I have found that a decided increase of blood pressure occurred after destruction of kidney substance by ligating. Thus in one animal, with an average pressure before operation of 90 mm., a rise to an average of 125 occurred after 100 days; and in another a rise from 117 to 150 mm. occurred after only 35 days. Janeway does not discuss the mechanism by which the hypertension develops.

Note.—I gratefully acknowledge my use of the literature of this subject as summarized by the following writers:

CLINICAL VALUE OF RECENT STUDIES IN EXPERIMENTAL NEPHRITIS *

HENRY A. CHRISTIAN, M.D.
Hersey Professor of the Theory and Practice of Physic, Harvard University; Physician-in-Chief, Carney Hospital
BOSTON

A symposium on nephritis at the present time quite fittingly is opened with a reference to the results of recent work in experimental nephritis. This, however, is not the case so much because the results as yet are of very great importance, but rather because it seems likely that the experimental method applied to the study of nephritis will in the future throw much light on the problems of the disease.

The history of the study of nephritis is not long. With Bright in 1827 begins our accurate knowledge. He it was who linked together in causal relation the symptoms, albuminuria and edema, and the lesions in the kidney. Keen observers added fact after fact for fifty years and more. Technical improvements widened the field of observation, so that a period, which we may arbitrarily end in the early part of the present decade, had contributed much to our knowledge of nephritis through the work of pathologists and clinicians. Yet our knowledge remained largely a knowledge of results rather than a knowledge of causes and progressive development, and many were the gaps in our knowledge, great the discrepancies between clinical observation and postmortem finding. In the present decade the experimental method has been applied increasingly in the study of disease in the hope that by it our knowledge of the life-history and causes of disease might be extended. Nephritis has been studied in this way and certain results have been obtained.[1]

I am not asked to review the numerous experimental studies of nephritis that have been published in recent years, but to indicate what clinical bearing, if any, this work has. If we turn to nephritis in man, we find the following phases of the disease of much clinical interest: the urinary changes, particularly the albuminuria and cylindruria, the uremia, the edema, the hypertension and associated cardiac hypertrophy, and, finally, the cause and the cure. Do our studies of experimental nephritis help in a better understanding of any of these? To answer this I will consider these points in the order named.

URINARY CHANGES

There has been a very general consensus of opinion with regard to albuminuria in nephritis. The albumin of the urine, in very large proportion, comes from the soluble proteids of the circulating blood and appears in the urine as a result of a pathologically increased permeability of the glomerular tuft. Degeneration of the epithelial cells of the tubules may have a small part in producing the condition. Experimental work confirms this view.

Cylindruria has received two interpretations. One of these assumes that the albuminous material constituting the cast arises from the albumin of the blood, which, after excretion through the injured glomerulus, becomes changed in physical properties so as to fuse together into a homogeneous coagulated mass, a cast. The other theory assumes that the albuminous material of the cast is derived from the albuminous material of the epi-

thelium lining the tubules, which becomes fused together and more or less homogeneous so as to make up a cast. This latter theory does not assume that there has been any very great change in the physical composition of the albuminous material between its cell origin and the cast, since cells and casts present in the urine show many identical physical properties.

The origin of urinary casts has been studied in nephritis produced experimentally. A variety of irritants, such as cantharidin, corrosive sublimate, uranium nitrate, potassium bichromate, etc., when given to animals, will produce changes in the kidney leading to the appearance of albumin and casts in the urine. Wallerstein,[2] among others, has conducted such experiments and concludes that all casts are formed from degenerated, disintegrated and metamorphosed tubular epithelium. Ribbert[3] and Schlecht,[4] on the other hand, studying the excretion of carmine through the kidney, have concluded that the hyaline casts are derived from the albumin excreted through the glomeruli, while the granular casts are derived from tubular epithelium.

In our laboratory at Harvard this subject has been investigated by Dr. R. M. Smith,[5] who employed rabbits and used a variety of irritants. Roughly, the irritants used may be divided into two groups: those which produce extensive changes of a degenerative character in the tubular epithelium (uranium nitrate, potassium bichromate and mercuric chlorid), and those which, [illegible] idence of acute nephritis, produce [illegible] changes in the tubular epithelium (cantharidin and arsenic). By varying the size of the dose of these irritants, by varying the number of doses, by varying the time interval between the doses, by varying the length of the experiment, which ends either in the spontaneous death of the animal or in killing the animal, it is possible very largely to control the lesions, and in this way there comes a manifest advantage in the experimental method as compared with a study of postmortem lesions in man.

It was found in this work that the irritants which produced marked degenerative changes in the epithelium of the tubules gave rise to a more abundant cast formation than did the other group of irritants. The urine of the animals employed, rabbits, was collected and the number and character of the casts was studied from time to time. By those irritants which produce most marked degenerative changes of the epithelium of the tubules most casts are produced, indicating that there is a close association between changes in the epithelium of the tubules and cast formation. By studying histologically kidneys of animals receiving different irritants in varying dosage, cast formation could be traced morphologically. The first change seems to be a granular degeneration of the epithelium lining the distal convoluted tubules, which increases in severity until the epithelium becomes converted into a granular material more or less completely filling the space bounded by the basement membrane of the tubule. This granular material is composed of remains of both cytoplasm and nuclear material. While this process is going on, fluid is presumably excreted through the glomerulus, so that there is a current of excreted fluid along the tubules which washes this granular material into the lower levels of the tubules. Toxic substances used in this way cause very slight degenerative changes in the epithelium lining the collecting tubules, and so the granular material washed down in the collecting tubules comes in contact with quite normal epithelium. In this process of passing along the tubule the granular material seems to become fused into plugs molded by the shape of the collecting tubule, and by the time the mass reaches the hilum of the kidney it is a well-fused granular plug, which floats out into the urine as a granular cast.

In the earlier stages of the process, urine analysis shows the presence of a number of casts, at first coarsely granular, later more finely granular. With a longer interval, or with a less intense local process, urine analysis shows casts more hyaline in character, and the sections from the corresponding kidneys show that in the lower levels of the tubules there are present plugs varying in homogeneity, and always in the older processes being quite distinctly hyaline. Even in the very chronic lesions, application of appropriate staining methods shows in these very homogeneous, hyaline, highly refractile casts the presence of numerous granules staining in every way identically with the granules that are in renal epithelium. So that from a morphologic point of view, supported by the results of urinary analysis, it would seem that both granular and hyaline casts in these animals arise from degenerative processes in the epithelium, and that the granular casts come early, the hyaline casts late, that there is a progressive transformation between granular and hyaline casts, and that granular casts appear to be formed quickly and excreted early, while hyaline casts are formed slowly and excreted late. These observations on animals are in harmony with the observed conditions in man, and would satisfactorily explain cast formation in most cases, though possibly not in every case.

Cast showers are occasionally observed in man. Experimental study has given some explanation of this. In Mackenzie's laboratory in Toronto[6] it has been found that in experimental nephritis, if, at a time after the casts have very largely ceased to appear in the urine, the renal artery is dissected out and physiologic salt solution is irrigated through the kidney under some pressure, a certain amount of fluid will be excreted through the ureter, and this will be found to contain a very large number of casts, largely hyaline in character. It would seem that, with a cessation of the active process, casts that have been formed have remained stored in parts of the tubules and gradually become hyaline in character; with increased flow of fluid through the renal vessels these will be washed out in large numbers. A similar acceleration of renal circulation with accompanying diuresis would in man similarly flush out a large number of casts and produce cast showers.

UREMIA

A number of theories have been advanced to explain the condition of uremia. Most of these assume the presence in the body of the nephritic of some toxic substance which, accumulating up to a certain point, produces the symptoms which we know as uremia. Attempt has been made experimentally to produce a similar condition in animals by means of nephrectomy, by ligation of the ureters, and by the administration of various irritants. In this way toxic conditions undoubtedly are produced which have some analogy to uremia in man, but the recognition in animals of symptoms, which may be regarded as truly uremic in the sense of this condition in man, is so exceedingly difficult that at the present time no great advance has been made, and it cannot be said that studies of experimental nephritis have thrown much light on the condition of uremia beyond giving support to the view that the condition is a toxic one associated with renal lesion.

EDEMA

From the earliest period of the work on nephritis the relation of edema to nephritis has been the subject of much discussion and investigation. The attempt of morphologists to correlate edema with certain types of renal lesion has been only very partially successful, and morphologic studies have yielded no explanation of the occurrence of edema. In recent years physicochemical methods have been applied and especial emphasis has been placed on salt retention with corresponding changes in osmotic tension. Analyses of food intake and urine output with respect to sodium chlorid seemed to show that in cases of nephritis with edema there was a deficient salt excretion and that the edema fluctuated in proportion to the salt intake. Widal and a group of French observers[7] have placed particular emphasis on salt-free diet as a means of controlling nephritic edema. A critical review[8] of the whole subject of the salt retention theory, however, seems to show that it is insufficiently supported. A considerable amount of experimental work is rather against it. Acute toxic nephritis in which there is no hydrops can be produced by various substances, and in these animals salt retention may take place. On the other hand, with uranium nitrate nephritis is produced in which edema is often present without there being any more salt retention than occurs in other types of toxic nephritis without edema. Recent careful clinical studies of Bittorf[9] and of Blooker[10] have failed to show any close relation between salt retention and edema. Renal cases without edema may exhibit a marked decrease in power to excrete ingested salt.[11] There is then undoubtedly a growing skepticism toward salt retention as a primal cause of nephritic edema, though in many cases it may be a contributing factor, and the withholding of salt from the food may be therapeutically effective. Many failures from this form of treatment, however, show its limited applicability.

On the other hand, there is increasing evidence to show that peripheral vascular lesions play a large rôle in the production of edema. This is not a new theory, but was advanced in 1877 by Cohnheim and Lichtheim[12] and more recently has been supported by Senator. It presupposes the presence in the circulating blood of some toxic substance capable of injuring the vessel wall. Some evidence of the existence of such a toxic substance is found in the experiments of Heineke,[13] Meyerstein[14] and Blanck.[15] These experiments were as follows: It is known that subcutaneous injections of uranium nitrate in rabbits will produce a toxic nephritis usually with edema, whereas other substances may be used to produce nephritic changes without any associated edema. Now if blood serum obtained from rabbits of the first group be injected into rabbits of the second group, edema appears, whereas normal rabbit serum produces no such result. Experiments of this kind are not constant in their results, but at least they are very suggestive of the importance of the rôle of circulating toxic substances in producing nephritic edema.

Pearce[16] has recently added further evidence in favor of the rôle of peripheral vascular lesions in the production of edema by a group of experiments in which he used known renal irritants and substances which are known to produce degenerative changes in the bloodvessels. Snake venom is such a vascular poison, and when given in association with a renal irritant edema results in a considerable proportion of the animals, particularly when moderately increased amounts of water are given by mouth, whereas the same treatment without the use of the vascular poison rarely results in edema. The functional studies of Schlayer, Hedinger and Takayasu[17] show that there is a close relation between the functional renal vascular disturbance and the edema.

Further evidence in support of the part played by vascular lesions in the production of nephritic edema is given by the results of my own histologic studies,[18] in which, in an examination of the kidneys of rabbits after the use of various renal irritants, I have found quite constantly associated with uranium nitrate lesions a change in the walls of the vessels of the glomerular tuft, consisting of the appearance in them of numerous hyaline droplets demonstrable by special staining methods. This vascular lesion was not found in kidneys of animals receiving substances other than uranium nitrate, and, as the uranium nitrate is the substance which produces in rabbits edema much more constantly than any other substance, it may be inferred that there is some relation between this anatomic lesion and the occurrence of the edema.

It cannot be claimed that the evidence is complete, but so far as the results of experimental work go it is very strongly suggested that the edema in nephritis results from injury to the peripheral vessels associated with changes within the kidney, probably in large part vascular also. Accepting this evidence, it is not surprising that there is no strict correspondence between the occurrence of edema in man and a definite type of anatomic lesion in the kidney. It is conceivable that various anatomic lesions under certain circumstances might lead to the production of functional disturbances in the kidney resulting in the retention or formation of toxic substances, which would injure the vascular apparatus and lead to edema formation, or it is possible that the same toxic substance which produces the renal lesion also is the cause of the vascular lesion. Much more experimental work, however, is necessary finally to determine the cause of edema.

HYPERTENSION AND ASSOCIATED CARDIAC HYPERTROPHY

Chronic nephritis is generally recognized as one of the common causes of high blood-pressure and associated cardiac hypertrophy, and a number of theories have been advanced in explanation of this condition. Some of these have been submitted to experimental test. Pässler and Heincke[19] have found that there is an increased blood-pressure and cardiac hypertrophy following the removal of considerable portions of the kidney substance, though these results were not constant. Janeway[20] has obtained similar results, though it is not very clear in just what way the blood-pressure is raised. Another group of observers have believed that the internal secretion of the kidney was a factor in raising the blood-pressure, and adduced in favor of this the fact that injections of extracts of kidney produced a rise in blood-pressure. A critical review of this work has been made by Pearce[16, 21] with additional experiments of his own, and he finds that results are very inconstant, and that the extract of the kidney of one animal may act in just the opposite way to the extract of the kidney of another species; consequently it is not believed that internal secretion in this sense can play very much part in producing hypertension. In the blood serum of animals receiving doses of certain substances that produce renal change there may be particular substances which have a pressor action. However, this type of work experimentally so far has been confined to acute conditions, though in man suffering from chronic nephritis numerous reports have been made indicating that there are substances in the circulating blood capable of acting to raise blood-pressure, but here again more recent reports give conflicting results, and probably not a very great amount of importance can be attached at the present time to these as factors in causing hypertension.

In a certain number of experiments in which the successful production of chronic renal lesions[22] has been attained, there is evidence of cardiac hypertrophy, and further studies along this line may yield results of importance. Since at the present time we have several experimental ways of producing cardiac hypertrophy, it may be possible to unravel the cause of this condition in nephritis. As shown by Fleisher and Loeb,[23] spartein and adrenalin chlorid will lead to the production of myocarditis with cardiac hypertrophy, and a moderate number of experiments in our laboratory have shown that the myocardial lesion in this condition as well as the findings in the kidney are quite different from those in a few animals where a type of chronic experimental nephritis has resulted from repeated injections of uranium nitrate, and in neither one of these groups of animals do we find the type of vascular lesion that Klotz[24] has obtained in Montreal by his method of increasing intravascular tension by inverting rabbits, from which procedure a marked degree of arterial change with dilatation of vessels is developed in the arteries of the anterior half of the body, associated with cardiac hypertrophy. Since these various experiments suggest that we can experimentally control the production of cardiac hypertrophy and obtain the result by producing chronic renal lesions, chronic myocardial lesions and chronic vascular lesions, it may be possible by such studies to arrive at the causal factor chiefly acting in any one of these types.

CAUSE AND CURE

As yet too little work has been done for the studies in experimental nephritis to throw much light on the etiology and treatment of nephritis. It is in the chronic nephritis that least is known about cause and cure. Experimental results in the production of chronic nephritis have been inconstant, and by nature such experiments are difficult. The repeated injection of various irritants has resulted in a certain number of cases in the production of lesions fairly analogous to the chronic renal lesions that we find in man. In animals, however, the remarkable recuperative power of the kidney makes the production of chronic lesions very difficult. Still, so far as results have been obtained, they suggest that in many cases chronic lesions in man result from continued action of small amounts of toxic substances, but throw no light on the cause of the appearance of these substances. Lead salts are about the only substances used experimentally which could in any possible way be similarly active in man, and it is not conceivable that lead-poisoning is a factor in the production of many cases of chronic nephritis. Some experiments seem to show that a single very extensive degenerative process in the kidney may result in the production of chronic lesions; and it may be that a few cases in man result in this way, just as at present it is believed that certain cases of cirrhosis of the liver are the result of some single acute degenerative process. Very little light so far has been thrown on the etiology of nephritis by experimental methods, however, and no assistance in the cure and prevention has been given.

It is evident from this review of experimental nephritis that the work has been just begun. It is being carried on at the present time in many laboratories, and we should take courage in the belief that from these experiments much of direct clinical value will come, and that by it our knowledge of nephritis in man will eventually be considerably widened.

Acute Cerebral Tremor in Young Children.—J. Zappert contributes an article on this subject in the *Monatsschrift für Kinderheilkunde*, viii, 133, 1909, reporting four cases personally observed, and tabulating fourteen others from the literature, all in infants less than 2 years old. His conclusions are that some anatomic lesion must be assumed in every such case, and that the idea of a toxic neurosis must be given up, at least so far as children are concerned. It is evident that transient changes in the meninges and cortex are a frequent accompaniment of infectious processes in children. As a rule they subside without inducing any clinical manifestations, or merely a mild general affection whose cerebral origin it is difficult to determine. This last category includes the cases of tremor under discussion. It is possible that autotoxins or infections may induce changes in certain brain centers, entailing the tremor. The latter is thus the expression of a toxic-infectious injury of the brain. Complete recovery was observed in all but two of the cases cited, the children in these two cases growing up imbeciles

MANAGEMENT OF UREMIA *

EDWARD F. WELLS, M.D.
CHICAGO

For the purposes of this discussion, uremia may be tentatively defined as an autointoxication, which affects mainy the nervous system, and occurs in connection with renal insufficiency. It is due to the retention in the blood, tissue lymph and cells of the body of certain indeterminate, but specific, products of perverted, or normal, tissue metabolism, which are not excreted by the inadequate kidneys, or are not taken up by the lymphatic radicles, or are not neutralized or destroyed by the lymphatic glands or other protective organs.

We are lacking in knowledge regarding many of those fundamental facts of anatomy, physiology and pathology which are necessary for formulating a specific treatment for uremia; therefore, that which is offered should be considered as being based on a fairly rational empiricism, directed in the main toward the prevention and relief of prominent symptoms and known conditions.

In order that my remarks may not lack in directness and force by a discursive rambling over too broad a field I shall confine myself to a consideration of some of the problems in the management of uremia, with particular reference to the disturbances of the intravascular and extravascular circulation, in that protean malady technically known as chronic interstitial nephritis, as they have been encountered in my personal experience.

Fairness impels me to say that the exigencies of this occasion renders it impossible to give consideration to the many interesting features connected with the treatment of such strikingly important symptoms as convulsions, coma, Cheyne-Stokes respiration, mental aberration, etc.

On making a diagnosis of chronic interstitial nephritis the physician should make earnest efforts toward preventing the development or recurrence of recognizable uremia. The patient should be informed of the nature of the disease, and given a tactful prognosis and directions for its management as to diet and general regimen. The diet should be individualized and specifically prescribed; it should be so arranged, along the ordinary established lines, as to maintain nutritive equilibrium at the highest possible level, with the smallest total amount of proteid and carbohydrate foods. The total liquids should be so adjusted as to carry off the largest amount of excrementitious materials, as may be determined from time to time. The regimen should consider such important matters as residence, clothing, occupation, exercises, environment, etc. The amount and character of the physical exercises must be adjusted to meet varying capacity and requirements. Extraordinary care should be taken to avoid infectious diseases. The patient should be seen with such frequency as to allow the physician to keep closely in touch with his ailments. At these times modern methods of examination should be the rule. The patient should consult his physician promptly on the advent of any one of a series of significant symptoms, a list of which he should have. The physician should be intelligent, alert, assiduous and tactful; in every legitimate manner he should endeavor to obtain and retain the confidence of his patient, solely because it is to the latter's best interests.

Mention is frequently made of the sudden and unexpected onset of uremic manifestations; but we may well inquire whether this is often really without warning. Looking back over my experience, I recall several instances in which an uremic attack was ushered in with a celerity which was, at the time, truly surprising; yet when these cases are reviewed in retrospect none was without ample symptomatic warning. Certain it is that when excessively high blood-pressure, various dyspneas, edema, transient blindness, retinitis and retinal detachments, dizziness, headaches, neurites, drowsiness, impairment of the sense of location, mental perversions, tremor and cramps, aphasia and fleeting paralyses, cardiac enlargement and insufficiency, vomiting and diarrhea, cutaneous affections, etc., thrust themselves, singly or in groups, obtrusively before us, we should appreciate their diagnostic significance.

As is well known, the blood-pressure is abnormally high in these cases. Perhaps the dietetic and other measures instituted may limit, or possibly prevent, further advances along this line. Rarely, as time passes, the vasomotor nerves so accommodate themselves to the unknown irritant that the circulatory balance is adjusted in such manner that the blood-pressure remains stationary, or even declines somewhat; and this without notable cardiovascular failure. The exalted cardiovascular tension may be somewhat reduced by various medicaments, as, e. g., hippurate of ammonia, lichenin, the nitrites, the iodids, thyroid extract, etc. The clinician must decide whether any measures should be taken to bring about this result; and, if so, under what circumstances, and by what means. Ordinarily the high tension is conservative and should not be interfered with. In some instances, however, there occurs a rapid rise of pressure above the patient's usual high level, with increase of the hazards accompanying this abnormal state. These sudden exaltations of tension are often followed by failure of the delicately balanced cardiovascular-areolar tissue supporting tension. Under these circumstances, with the patient in great distress, rupture of degenerate vessels threatening, and a practical certainty that circulatory incompetency will soon occur, I am of the opinion that the patient's best interests are served by anticipating the near-inevitable by artificially lowering the excessive pressure—if this can be effected. If the condition is urgent a free blood-letting should be done; otherwise one of the slower methods may be chosen. In this manner the patient is given the greatest relief, and imminent danger averted; but the underlying conditions remain, and the physician should not be lulled into a sense of security, as the patient is likely to be, by the ease and comfort which is now his. Experience proves that, once lost, the complicated circulatory balance is seldom fully and permanently restored. Not infrequently circulatory insufficiency follows an acute infection, or other depressing influences, without the patient experiencing the extreme tension referred to. In such cases the hypertrophied heart dilates, valvular incompetence may be added and the well-known results of cardiac failure appear, possibly to an overshadowing degree. In this connection especial consideration should be accorded to the overfilling of the lymph spaces, and the subsequent failure of the areolar tissue-lymph tension, with edema as the final result.

The rôle of edema in the genesis of uremia is most important, although it will be practicable, in this paper, to note only some of the most significant features. Thus, in many cases, without gross evidences of edema, the intercellular and areolar tissue spaces become distended with lymph to a degree which induces a high tension.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The patient is plump; the soft parts are resistant to pressure, but without pitting; the integrity of the areolar tissues as a series of restraining membranes is maintained; anasarca is not present, but is imminent; the condition might be termed occult edema. Under these circumstances the lymph circulation is impeded, and toxic waste products and specific toxins begin to accumulate, with uremia probably in its incipiency. Edema in chronic interstitial nephritis is usually of the incipient or occult variety, and infrequently does it become obtrusive; general anasarca is rare in uncomplicated cases; when dropsy becomes a prominent feature it is due to cardiac incompetency, and partakes of the general character of cardiac dropsies, with one important and fundamental exception, i. e., that the patient is more or less uremic. The bearing of this distinction on our conception of the essential nature of uremia should be given full weight. Thus it follows, logically, that, inasmuch as the physical conditions are alike, the uremia of the cardionephritic dropsical patient is due to vital, and not to mere mechanical disturbances. It is significant that, in my limited experience, the serum obtained from the liquid bowel movements of such nephritic patients has been much more heavily laden with chlorids, and often with sulphates also, than in others with pure cardiac dropsies.

Edema interferes greatly with the composition of the blood and the extravascular lymph, and with cellular nutrition. The capillaries and lymphatic radicles are compressed, with interference with their functions; the tissue lymph becomes stagnant and laden with specific toxins and tissue-waste materials; the extravascular circulation is short-circuited. There is an extraordinary lack of easily obtainable information concerning the physiology and pathology of the circulation of the tissue lymph. For our purposes let it be assumed that the nutritive elements of the blood, proteid and other, in aqueous solution, are transfused through the capillary walls by selective vital cellular action, assisted by simpler mechanical forces; that the extravascular lymph, carrying both nutritive and waste materials, circulates, vitally and mechanically, in the intercellular channels and areolar tissue storage spaces, and by a selective excretory function of the cells of the lymphatic radicles, finds its way into the ducts and thence through the glandular protective filters into the blood current.

In my opinion, special consideration should be accorded the management of every degree of edema—occult as well as manifest—in nephritics. As the result of long-continued and fairly broad observation I commend the following plan of treatment, modified to meet varying and individual conditions:

During the first day the diet should consist of thin gruels, cream and water, vegetable soups, tea, coffee, cocoa, water and carbonated waters. From these there should be omitted the gruels on the second, and soups on the third day; during the fourth and fifth days very little should be taken; on the sixth day the soups should be replaced, and on the seventh day the gruels; later the ordinary careful dietary of the nephritic should be gradually resumed. Every night of the first three days the patient takes 10 grains of mercurial mass, in two recently made pills of 5 grains each, followed by an efficient sodium or magnesium saline in the morning. Beginning on the fourth morning, after free action of the saline, there is given 1/30 grain pure elaterin hourly for three doses; 1/24 grain every two hours for three doses; finally 1/18 grain every three hours until ten or twelve copious watery bowel movements have been induced. During the last series of doses the intervals may well be p. r. n., or as specially directed. Subsequent to the discontinuance of the medicine there will be several more of the liquid evacuations. The elaterin must be pure, and it is preferably given in powder, with sugar of milk and finely powdered ammoniated glycyrrhizin. During the time the elaterin is being given the patient should remain in bed, using the pan. He should be informed of the abdominal distress, nausea and vomiting which the drug sometimes induces. Without giving reasons for the opinion I am quite sure that, if satisfactory results are to be secured, it will be well to follow closely the spirit of these suggestions in regard to diet, medicine and general regimen as detailed.

The treatment here recommended will usually drain from the bowels a considerable amount of serum, varying in total volume from 4 to 15, or more, pints. The serum is usually acid; straw-colored; of from 1005 to 1030 specific gravity; free from albumin; laden with urea to 0.01 per cent. to 0.2 per cent, phosphates to small percentage, chlorids to 3 per cent. to 25 per cent. and sulphates to 1 per cent. to 10 per cent., by volume. The odor is sometimes peculiarly offensive. There is no doubt, in my mind, as to the fact that the serum passes into the intestine by secretory action.

During the period of alvine drain renal activity is reduced; subsequently the flow of urine usually becomes very free, often continuing so for many days, even until the cardiovascular-sanguineous and lymphatic-tissue lymph balance of the circulation has been restored. In the most successful cases the urine is not only increased in quantity, but in urea content as well—rising in one instance to the enormous output of 994 grains during a single twenty-four-hour period. In some unsatisfactory cases—rare in my experience—the flow of urine is not augmented; the overstretched areolar tissues fail to regain their resiliency; the current of tissue lymph toward the lymphatics is not maintained—possibly it had not been attained; edema continues or increases.

This initial part of the treatment, in typically successful cases, is followed by subsidence of the objective and subjective symptoms—uremic as well as circulatory—with such relief to the patient that it may be fairly described as profound. Much of the improvement appears promptly; more is noticeable during the following two weeks; the full measure of benefit, however, is not obtained until about the end of six weeks, and a surprising proportion during the last few days of this period. The improvement usually continues for several months; it may be of short duration; occasionally the period is remarkably extended.

In whatever manner the relief may have been induced it is probable that it may be made more complete and greatly prolonged by close medical supervision and persistently careful management. For this reason I have, for many years, advised these patients to take daily systematic, well-considered and individualized, active exercises of such character as to bring into play as many as possible of the muscles of the body. Whenever necessary this is supplemented by general and vigorous massage. The object of these measures is to facilitate, forcibly, cellular activity. The results have been so satisfactory that I commend these methods for consideration.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CHRISTIAN, MUSSER, VAUGHAN AND WELLS

Dr. D. L. Edsall, Philadelphia: It is very clear that a great many erroneous conclusions have been reached in the vast amount of literature that has accumulated on this question. There is no constant relation between the retention of chlorids and edema and the severity of the nephritis. There are, then, various reasons why the theories concerning the extremely intimate relation between edema and the chlorid disturbances are not established. There are also errors in regard to the conception of the cause of alterations in chlorid excretion, for reduction may, on the one hand, clearly be due to a reduction of the capacity of the kidneys to excrete chlorids, while in some instances it is certainly due to alterations in processes going on elsewhere than in the kidneys; and at times the latter are probably definitely conservative processes, designed to relieve the kidney of its work of excretion, and the edema itself becomes a conservative process, partly to relieve the kidneys and often largely to relieve the circulation. A reduction in the amount of sodium chlorid ingested, aside from any influence on edema, helps largely to reduce the work that the kidneys do.

I saw this fact strikingly illustrated some years ago in some experimental observations I made in regard to the possible value of studying the excretion of definite doses of sodium chlorid as a means of testing the functional capacity of the kidneys. I gave sodium chlorid to various persons who appeared to have about the same degree of damage of the kidneys, some of them having actual nephritis and some of them simply arteriosclerotic changes. I several times met with observations which made me give up the studies because it was clear that there was danger attached to such a test; that is to say, I found in several instances that an amount of sodium chlorid no more than equal to what is taken in an ordinary diet, produced evident and sometimes marked increase in the incapacity of the kidneys to carry out not only the excretion of sodium chlorid, but excretion in general, of water as well as of the solids, was largely cut down. It is clear then that an amount of sodium chlorid not more than equal to what is contained in an ordinary daily diet may cause decided failure of function on the part of the kidney even in cases in which the kidney appears to be doing fairly good work. Hence, whatever we may think concerning the theories of the relation of salt to the symptoms of nephritis it is certainly a valuable procedure to limit the amount of table salt in the diet. This same point has been elicited in another way recently in some work that Dr. Lavenson has been doing in my laboratory in regard to the influence of certain potassium salts on the excretion of chlorids in the urine, basing this work on the statement of Bunge, which has not been generally accepted, however, that potassium salts cause a decided increase in the excretion of chlorids. There seems to be little doubt that Bunge is right about this, for Dr. Lavenson found a decided increase in chlorids after a variety of potassium salts. The nitrate which has been considered to have an especial action did not appear to be particularly active as compared to the others, the effect exerted being apparently in direct relation simply to the amount of potassium given. Dr. Lavenson naturally tested the suggestion that at once comes from this that potassium salts might be a good method of overcoming chlorid retention. The result proved to be merely an instance of the fact that when we attempt to do what superficially appears to be right, we may do harm. The retention of chlorids appeared to be in some cases definitely a protective thing, and urging the kidneys to excrete more chlorids simply did harm, the general excretion being reduced, although the chlorids might increase or decrease—actual toxic symptoms developing in one case in mild form. There is one more point that I would lay stress on: That is, we should approach all these conditions with the idea that they are largely dependent on intoxication and the best way to relieve intoxication is to start by relieving the amount of work demanded of the eliminative organs as far as we can. Satisfactory results can sometimes be obtained in these cases by placing the patients on actual starvation for a brief period, sometimes a day and sometimes several days. This gives an opportunity for improvement in the digestion and the metabolic and excretory functions through giving them a partial rest. It is of course necessary when carrying on starvation for this or any other purpose to be very watchful of the effects, as it is a serious procedure, but in these cases it is necessary to undertake serious measures, and the reduction of the diet to nothing but water or to say a pint of skim milk in a day, to which water is added, will sometimes accomplish very comforting results, which are not obtained when an ordinary full milk diet is used.

Dr. Delancey Rochester, Buffalo, N. Y.: There are two practical points I should like to speak about. First, it strikes me that salt-free diet is valuable in those cases in which there is much edema, because of the fact that in the fluid and in the tissues of the body there is a considerable amount of sodium chlorid which will supply its needs. Dr. Vaughan has shown that the tissues of the body need chlorids to a considerable extent; if we withhold them from the food, Nature has provided a source of supply in the serum of the edematous fluid, which may be called on when they are in demand. I should think that if the fluid ingested be restricted, fluids could be obtained from this same source. Second, in the management of uremic attacks I wish to commend Dr. Wells' procedure, but in addition, there is one thing used in these cases which I find of special value—the action of the skin as an eliminative organ. I have found it very useful to administer, ten or fifteen minutes before giving the hot water bath or hot pack, minute doses of pilocarpin, 2 or 3 mg., it aids greatly in producing profuse sweating in these patients. Elaterium has also been recommended. I have used it in smaller doses and continuously—perhaps 8 mg. twice a day. It does not produce nausea, but drains the bowels and is of great advantage in these cases.

Dr. James Tyson, Philadelphia: Dr. Christian's paper was one which has so thoroughly covered the lines with which I am practically familiar that I hesitate to say anything on the subject or on what he has brought out. I was struck, however, with the apparent differences of result in experimental nephritis as compared with the symptoms that are observed clinically. I was also impressed by what was said as to the sorts of casts which first make their appearance in producing experimental nephritis. In actual experience the cast that appears first is usually the hyaline cast, and not the granular cast. This is seen in the passive congestion due to cardiac disease which permits a leakage. As the seriousness of the condition grows the granular cast appears, becoming more and more granular, *pari passu*, with the destruction of the cells. What Dr. Christian has quoted as experimental facts are probably correct, but they do not agree with my experiences in the study of the urine in actual cases. With regard to the treatment of high tension, Dr. Musser has struck the keynote, but not enough stress was laid on the impropriety of treating high tension *per se*. To strike at the root of the evil, one must remove the cause of the high tension. In this respect, Dr. Edsall's statements on the matter of starvation are sustained by my experience. Many years ago I taught the treatment of nephritis by small quantities of milk, or as little food as possible. This was not for the purpose of relieving the uremic symptoms any more than to remove the edema and the vascular symptoms of an unfavorable kind.

Dr. John A. Lichty, Pittsburg, Pa.: When a slight cerebral hemorrhage occurs in these cases, the blood-pressure immediately drops and remains down a longer time than one would expect it to do when rest is ordered. There is no trouble at all in keeping the blood-pressure, which was 265, down at 195 or 210, while the patient is leading a rather active life. These patients are of course thoroughly frightened and are willing to follow a regimen now of rest, diet, etc. But the drop in the blood-pressure is very sudden and will remain lower for a longer time than one would expect.

I should like to refer to two patients with chronic appendicitis whom I have had operated on during the past year in which there was a history of nephritis of some years' standing; I of course had to consider the safety of an anesthetic. Ether narcosis produced absolutely no disturbance of the urinary secretion. The first patient was 24 years old and had

had scarlet fever when 3 years old, and was afterward sent to Dr. Tyson of Philadelphia and Dr. Janeway of New York, because of the existing nephritis. Albumin and casts remained in the urine year after year. It was decided that an interval operation for appendicitis should be done. Very great care was taken in giving the ether, and there followed no disturbances in the urinary secretion at all. The second patient, twelve years ago, had had diphtheria and a general anasarca afterward. Dr. Osler saw this patient and pronounced the condition a very severe case of parenchymatous nephritis. This patient also had to be operated on for appendicitis. The ether narcosis had no evil effect on the kidney secretions.

A third patient, however, with no signs of nephritis, did quite differently. This patient had normal urine, and was operated on under ether narcosis. After the operation there appeared an acidosis, casts, albumin, etc., and death due to anuria occurred within twenty-four or thirty-six hours after the operation. With such diverse experiences it seems to me that after all our knowledge of this condition, so far as it applies to the individual patient, is not of very great practical value.

DR. JOHN N. UPSHUR, Richmond, Va.: I want to protest against the administration of morphin or any opiate as a temporary palliative in the treatment of uremia;; it certainly does interfere with secretion. The thing we should do in cases of grave uremia is to direct our work as much as possible along lines of safety; therefore, if we can give rest to the kidneys and at the same time get elimination we can accomplish much more and do much better than if we get our head in the bushes like the ostrich, by giving morphin, and think we are accomplishing something.

If we can give rest to the kidneys by placing the patient in a hot pack and by hydragogues cause elimination through the bowels, we will find that we not only give relief from the grave uremic symptoms, but through the elimination through the skin and bowels at the same time we can reduce the amount of tension in the blood vessels. The error we are liable to fall into in patients who may and do have renal trouble, is that we do not make sufficient analyses of the urine and do not get the careful knowledge of what is going on by such a systematic urinary analysis. We are all apt to err in this direction. Even in those cases in which there is no suspicion of renal lesions we should keep in touch with the condition of the kidneys by a careful observation through urinary analyses; this should be made a routine matter.

DR. WALTER L. BIERRING, Iowa City: It seems to me that sufficient emphasis has not been given in this discussion to the special reference made by the last speaker in the symposium on the relation of circulatory disturbances to uremia. Whatever conception we may have as to the nature of uremia I am sure we recognize that the appearance of its symptoms is largely dependent on the maintenance of the cardiovascular balance, and the real problem of treatment at the present time is to anticipate and control, so far as possible, the cardiovascular disturbances.

DR. HEINRICH STERN, New York: Dr. Christian mentioned in parenthesis that the excretion of albumin via the kidneys can only ensue on the basis of a diseased condition of the latter. Evidently he has not consulted some of the latest literature on this subject.

It is not a diseased kidney which permits the transudation of the albumin, but a strong and healthy kidney. I should say that the healthy kidney is always permeable for the albumin molecule, but that the blood which attaches itself to the albumin and then deposits it in the tissues whence it is again taken up by the return circulation in the form of urea, does not permit the escape of the blood proteids prior to their intrasystemic disintegration. While, therefore, albuminuria is a pathologic occurrence, its causative factors are not situated in the kidneys but are distinctly anterenal.

Although Dr. Wells has not brought out anything substantially new, he has developed some new view-points and interpretations. I know that he has not especially entered into a clinical subdivision of the uremic states. I think, however, that it is impossible to apply rational treatment unless one knows the basis on which the uremia has developed. For instance, in the large white kidney, the passage of urine is seriously interfered with; in contracted kidney, on the other hand, there is nothing to prevent its excretion. The sera of uremia on the basis of chronic parenchymatous nephritis are differently constituted in some major points from those of uremia due to interstitial nephritis. In parenchymatous nephritis there is a tendency to convulsive phenomena, in interstitial nephritis to a comatose state. This important divergency is explained by the different constitution and physico electric behavior of the respective sera. I have shown that there is no chemico-toxicity which stands at the foundation of the uremic phenomenon, that there is not a single substance, known to us, excreted by the urine or the other excrements, which is apt to bring about either the convulsive or the comatose phenomena. By retention nitrogen in the blood is understood all the nitrogen remaining in the liquid after complete removal of the albuminous substances. The average amount of retention nitrogen in 100 c.c. of normal blood serum is between 25 and 30 mgs.; in chronic parenchymatous nephritis without uremia the average amount is 40 mgs. and in the presence of uremia about 62 mgs. in 100 c.c. blood serum; in chronic interstitial nephritis without uremia an average amount of 82 mgs., and when uremia prevails 130 mgs. retention nitrogen were found. These figures show that in the blood serum of chronic parenchymatous nephritis about 35 per cent. more retention nitrogen is contained than in the normal liquid; that in interstitial nephritis the retention nitrogen is present in twice the quantity as in the parenchymatous variety, and that the retention nitrogen is augmented in the uremic states consequential to the nephritic conditions. The enormous amounts of retention nitrogen in the serum of chronic interstitial nephritis undoubtedly stands in causative connection with the natural termination of the disease-uremia. In parenchymatous nephritis uremia is not only a much rarer but also a less grave complication. This I have explained by the fact of the relatively small amount of retention nitrogen. The inconsistency of pursuing the same plan of treatment throughout in the various cases of uremia which are so unlike in their manifestations and have risen from such distinctly discrepant substrata is obvious. I think it is unwise to speak of the management of uremia, when this uremia may mean that we may have at least two entirely different states to deal with. One cannot be treated like the other.

Some one said that morphin was contraindicated in uremia. This has to be taken with a grain of salt. In the uremia of chronic interstitial nephritis, which is characterized in almost every instance by a condition of tranquil coma, very rarely exhibiting convulsive phenomena, morphin is certainly contraindicated, because it also causes coma and may thus aggravate the existing comatose condition and hasten a fatal issue. On the other hand, in the uremia of chronic parenchymatous nephritis, which is characterized by convulsive seizures, morphin may have a distinct value when chloroform has proved of no avail. Its efficacy in controlling the convulsions may be due to the retardation of the metabolic processes ensuing from its administration, thereby preventing further accumulation in the blood of catabolic substances, and to its augmentation of vascular tonicity.

DR. BOARDMAN REED, Los Angeles, Cal.: I wish to confirm the observations of Dr. Tyson of Philadelphia and Dr. Smith of Baltimore regarding the value of therapeutic fasting or starvation, not only in fevers but in other conditions. We know that in gastric ulcer and, in my experience, in hyperchlorhydria, the good results which follow starvation for a few days when the patients are put on a light diet, particularly in patients with high tension. In treating patients with arteriosclerosis and hypertension splendid results follow placing them on a low diet, or even actual fasting for three, four or five days. In cases of high tension it is perfectly safe, particularly if the pulse be watched carefully to see that the tension does not get too low. Only recently we have come to appreciate what can be done by fasting for a few days, and particularly its influence on conditions in the gastrointestinal tract. It seems to be the only way so far discovered of getting rid of the bacterial cause of the trouble in certain cases.

Dr. Hugo A. Freund, Detroit: I find that too little mention has been made of the value of observing hypertension systematically. This one thing as suggested by Dr. Bierring should be carefully watched in each case we are treating. It is very essential to note the condition of the cardiovascular system in connection with the urinary findings. I do not believe, however, in the desultory examination of the blood-pressure with the sphygmomanometer, taking the blood-pressure one morning, then the next, and so on, but I do urge its systematic use. A competent nurse or assistant can be trained to take two-hourly readings. These, when charted, give us most valuable curves that aid in the immediate treatment and in the prevention of otherwise unavoidable accidents. In many cases an oncoming uremia is shown a long time before the patient is seized with convulsions or other disturbances make their appearance.

Dr. Charles F. Hoover, Cleveland: It has not been clearly stated whether we are dealing with a cardiovascular problem or an impairment in renal elimination or uremia. There seems to be a lack of clearness on the part of the speakers as to what phase of nephritis these therapeutic efforts have been directed.

Dr. Henry A. Christian, Boston: In the paper I simply discussed the acute toxic nephritides. If an animal be given a small dose of these irritating substances and then examine the urine you will throughout the course of the observation find in the urine simple hyaline casts. It does not follow that those casts have been hyaline from the beginning of formation. It simply indicates that a considerable time has elapsed between what has been formed in the kidney and what appears in the urine. If certain cases of cardiovascular disease be observed, we all know that only hyaline casts will appear during the time of observation of this condition unless there is an acute exacerbation when the granular casts appear. Apparently from experimental work the following explanation will serve for these cases. The casts are formed in small quantities, and the formation takes place slowly because the irritant used is small in amount, or the irritant present in the human body is small in amount. The casts do not make their appearance in the urine for a considerable period of time. In the time elapsing between their formation in the kidney and their appearance in the urine they have become homogeneous and consequently hyaline. This condition can be repeated with ease in animals. There is no discrepancy between the clinical and the experimental findings. Two factors must be considered, the time relation of cast formation, and the time relation of cast excretion. It is the period between these two occurrences that determines whether the casts will be hyaline or granular. At the same time it must be acknowledged that there is always a chance for error in arguing from animal experimentation directly to man. So far as we are able to judge, the method of formation of casts in animals is probably the same as in man; but of this, however, we are not certain. It was my intention in the paper to adhere to the consideration of the title, "Experimental Nephritis," and no mention was made of various other types of edema and renal lesions because this was considered beyond the scope of the paper. Albuminuria without renal lesion, as referred to by Dr. Stern, has so far as I know, never been produced in animals, and anyhow is hardly a part of a symposium on nephritis.

Dr. John H. Musser, Philadelphia: We must remember that hypertension is a curative process; therefore, any attempts to remove it entirely, especially after degenerative lesions secondary to the process have arisen following the intoxication, will be and should be in vain. What we must do is to reduce such hypertension to the normal for that individual. I have made the same observations as has Dr. Lichty in regard to the fall in the blood-pressure and the persistence of that fall after an attack of apoplexy. In subsequent attacks the fall is very great, and it is probably due to the attack. Afterward the blood-pressure does not rise to the same point. In considering the treatment, I did not refer to the dietetic management so strongly as I should, especially in regard to the limitation of the amount of food taken and the proper selection of food. One must rely on the results of a study of the function of the stomach in determining the line of diet, plus the general broad principle of the limitation of the amount given. I want to refer to the use of two drugs. First, iron which is administered not only for the hypertension but for the degenerative lesions that accompany it. This remedy is of the greatest value. It is not only, it appears to me, a drug which supplies iron to the blood, but it also has some nutritional effect on the cellular structures. Undoubtedly iron does, as observed years ago, lower the blood-pressure when its use is prolonged. In cases of myocardial disease, and indeed I might say in cases of cardiac disease with dilatation, if I had to decide in an emergency of acute dilatation what remedy to use, I would prefer iron to digitalis. This agent, however, should be kept up for a long period of time. I should like to refer to opium as a remedy of great importance for the neurosis which attends this condition, either as a factor secondary to the intoxication or secondary to the hypertension. Small doses of opium or morphin give most satisfactory results in securing that equanimity which is so necessary; it aids in keeping down the stress and strain incident to the increased blood-pressure. Finally a word in regard to the use of mineral waters or the purgatives we select. Unless we are very circumspect in this matter we will find patients taking purgatives containing too much sodium chlorid and bring about renal inhibition. I recently saw a case in which a large amount of saline purgative was used when it was not indicated; the result was a progressive increase at that time of renal insufficiency and consequently dropsy. Stopping the salt was sufficient to bring about the renal activity and a subsequent lessening of the amount of dropsy.

Dr. Edward F. Wells, Chicago: It should have been noted that I limited my paper to the discussion of certain clearly outlined conditions, i. e., uremia as it appears in chronic interstitial nephritis, with special reference to the lack of balance of the circulation and especially the extravascular circulation and the tissue lymph. This was done for the reason that in the fifteen minutes at my disposal it was impossible to go into all the different varieties of uremia, and the prevention of its causes. In my paper I laid particular stress on one point, or one sentiment, namely: the patient should be nourished to the highest attainable level with the least possible amount of food; and this applies with particular force to the proteids and carbohydrates ingested. It is astonishing to those who have not given much attention to the matter how comparatively little food is required for this purpose. Patients can be nourished on two-thirds, one-half or even one-third of what they are accustomed to take and maintain their weight, retain their vigor and increase their sense of well-being; this I have demonstrated in several instances. The trend of my remarks is this: The oncoming of uremia is manifested clearly by shadows cast before. One of the most significant of these foreshadowings is an endemic state, or usually an occult edema, in which the intracellular spaces are distended with fluid, and to a high tension. Such patients may be deprived of the excess of extravascular liquid with the loss of from five to twenty, or more, pounds in weight in a few days. Certainly this total loss in weight is due wholly to the loss of liquid and not to that of fat or the solid tissues of the body. In the cases in which the edema is occult, more or less manifest, I believe this to be an extremely important matter. The extravascular fluids contain an abnormal amount of certain salts, markedly differing from the proportions ordinarily contained in the lymph; therefore, the extravascular circulation is either overlooked as a whole, or portions are short-circuited. This is demonstrable in anasarca in which the legs are edematous; if indigocarmin be injected in the leg, it may be a very long time before it appears in the urine, and hours before it is noticeable in the serum of the opposite leg, or the serum may be drained from the opposite leg without getting a trace of indigocarmin. It has been short-circuited. It is to this condition that I wished particularly to call attention, not only because of its importance, but because I believe that it is either not sufficiently recognized, or due attention has not been given to it. The method of drawing off the liquid through the intestines is one of the many measures for the reduction of the edema which may be adopted; but on the method employed will depend its success or failure. If one gives elaterium he is sure to be uniformly dissatisfied with the results, but if he will follow the lines suggested definite results will be attained. With regard to occasional starvation, this, too, is a method which can be used, and is an essential feature of the method advised in the use of elaterium. The patient is practically starved; but he can live a long time without the ordinary foods. However, one may drive the nutritive portions of the blood out into the intracellular and lymph spaces; but stimulating the cellular secretory action in order to induce a return flow of the waste-laden and toxic lymph back into the general vascular circulation is not such a simple procedure. The serum obtained through the intestines by the use of elaterium is in the nature of a vicarious elimination, which is brought about by secretory action and not solely as the result of pressure. The fluid may be readily obtained clear by filtering, and is free of albumin; there may be a mere trace of it perhaps, but when such is the case it is accidental and due to the open spaces left by broken-down epithelium. The tissue lymph is albuminous and contains salts in a different proportion than is found in the serum drained off through the intestines.

OVARIOTOMY AND MYOMECTOMY EARLY IN PREGNANCY, WITH FULL-TERM DELIVERY*

H. GRAD, M.D.
Assistant Surgeon of the Woman's Hospital
NEW YORK

The relation of sterility and fibroids of the uterus has been widely discussed and two opinions defended by the opponents. One teaches the theory that the sterility is due to the growth in the uterus, while the other insists that the tumor is the cause of the sterility.

As the cause of tumor formation in the uterus is not known, the opinions expressed are but a speculation. One opinion is entitled to as much consideration as the other.

Fibroid tumors of the uterus are found in women under different modes of life; the married, the unmarried, the sterile as well as the fruitful are subject to this disease. These tumors are found in women who have suffered infection of the genital tract, and also in those who have never had an infection. They are found in the virtuous as well as in the morally lax, in the virgin as well as in the sexually promiscuous. In some cases the tumor appears early in life, in others later. The growths occur in women living in luxury as well as in their sisters of hard toil. They occur in women of all races, although the colored race is said to be more liable to these tumors.

It is not known to what extent the physiologic congestion occurring periodically in the genital organs during menstruation is responsible for these tumor formations, or if a responsibility can be put on this function at all.

In this connection there is a case on record by Sutton[1] which is of interest. In this case a tumor supposed to be a fibroid was present for ten years in the uterus of a childless woman, twice married, who had never menstruated or shown any evidence of physiologic ovulation.

Emmet,[2] who has studied the subject of disturbed menstruation in fibroids and their relation to sterility, expresses himself as follows:

> Between the ages of thirty and forty years the unmarried woman is fully twice as subject to fibrous tumors as the sterile or the fruitful. I have already pointed out that this is one of the tributes which an unmarried woman pays for her celibacy. It seems as if it were the purpose of Nature that the uterus should undergo the changes dependent on pregnancy and lactation about once in three years throughout the child-bearing period, and that if the uterus is not physiologically occupied in child-bearing a fibroid will the more rapidly develop into a fibrous tumor as the woman advances in life. This will also be the case with the married woman who has taken means to prevent conception, as well as with her who has been sterile from some cause beyond her control, but to a less degree in the latter case. Finally, the woman who may have been fruitful in early life may have a tumor develop, but is less liable thereto from having once borne a child.

On the other hand, Haultain[3] holds that "sexual excitement in marriage favors the growths of fibroids; that fibroids tend to prevent child-bearing, and, further, that pregnancy in many cases, by promoting their growth, prevent conception in the future."

A fibroid tumor may lie dormant for a long time in the uterus of a sterile woman; she may then conceive, and with the conception the tumor grows and becomes an active factor in causing an abortion of premature labor later in the pregnancy.

A case of this kind came under observation last year.

CASE 1.—*History.*—Mrs. G., aged 35, had been married fifteen years. She had one child two years after marriage but had not conceived since. She had a small fibroid in the uterus, the existence of which she had known for many years. The tumor never produced any symptoms. Six months previous to my examination she stopped menstruating but did not think that she was pregnant. The amenorrhea extended over four months; then she began to flow moderately. At first she thought it was a menstrual period; the flow continuing over six weeks convinced her that something was wrong. She consulted her physician, who called a consultation. Under a light chloroform narcosis a large tumor complicating a pregnancy was made out. She was transferred to the hospital for observation, where a few days later she delivered herself of a five months' fetus. The placenta not coming away satisfactorily, she was narcotized, the placenta removed and the uterine cavity thoroughly explored. With the hand in the uterus a fibroid was palpable, which projected into the cavity of the uterus, undoubtdly causing the premature labor. It was hoped that with the subinvolution of the uterus the tumor would return to its previously quiescent state. Instead of that the patient kept on flowing.

Operation.—Seven weeks later, on account of severe metrorrhagia and anemia, the patient was operated on and a panhysterectomy performed. On opening the specimen it was found that the uterus had involuted perfectly but that the tumor extended clear through the uterine wall and projected into the cavity of the organ, causing the persistent metrorrhagia.

Here we have a dormant tumor awakening into activity by the conception, and by its rapid growth causing a premature labor and also bringing about symptoms that called for hysterectomy.

While there is a distinct relation between sterility and fibroids of the uterus, the underlying cause of this relation is not known. There are cases of pregnancy on record in uteri that apparently were hopelessly destroyed by myomatous tumors. Under what conditions does pregnancy occur in organs so overwhelmingly damaged by fibroids?

A most interesting case of this kind was reported by Dr. I. S. Stone[4] at a meeting of the Washington Obstetrical Society. The tumor consisted of a large mass of myomata of varying sizes, which he had removed from a woman six weeks pregnant. The uterus was entirely hidden from view by the surrounding nodular masses. The patient was 30 years old and had been married less than six months. She had been subjected to a conservative myomectomy four years previously. A most difficult and complicated problem confronted the surgeons when the abdomen was opened. The transverse colon was adherent to the growth and all of the omentum was sacrificed in its removal. The adnexa were firmly adherent and hopelessly diseased. The entire uterus was removed save a rim of cervical tissue. The case is one which shows how the most decided changes in the uterus itself, as well as the endometrium, may not prove a hindrance to impregnation.

In regard to adenomyomatous tumors of the uterus, Cullen says[5]:

> The disease is most prevalent between the thirtieth and sixtieth years; it does not in any way tend to sterility. . . . Our experience goes to show that neither an infantile condition of the uterus nor sterility is in any sense a prominent feature with these tumors.

Fibroid tumors may cause sterility by mechanical means. The tumors may distort the uterine canal to such a degree as to obstruct the onward movement of the spermatozoa, or by irritation set up an endometritis, the discharges of which become inimical to the life of the fecundating cell. A tumor may so dislodge the cervix uteri as to make it inaccessible for the semen, hence the sterility. A fibroid, particularly if it is a submucous growth, may keep up a state of congestion of the mucous membrane, this extreme vascularity being unfavorable for the implantation of an impregnated ovum, and hence the sterility.

The cause of benign growths in the uterus not being known, who can say but that the same conditions that are responsible for the fibroids may also cause the sterility? A woman, for example, is fruitful for many years, stops bearing children and develops a tumor. Who can say but that the same factor is responsible for both the tumor and the sterility? Pregnancy is not a simple affair, but the result of a delicate mechanism, and so delicate a mechanism as the fecundation of an ovum must depend on a variety of conditions and not merely on the meeting of the ovum with the sperm cell; hence anything which disturbs this delicate mechanism may be the cause of the sterility. It can not be denied that pregnancy favors the growth of fibroids and that future pregnancies may be interfered with by the greater enlargement of the tumor. We also see cases of conception with fibroids after long periods of sterility.

In considering the subject of sterility, whether the patient is suffering with a tumor or not, there is one thing to be borne in mind, and that is the competency of the male partner. This factor can necessarily never be left out of consideration, and if due attention were given to this subject in every case of sterility with fibroids of the uterus we would find that a large number of these women are sterile because the male partner is incompetent. The competency or incompetency of the male partner has still another bearing on this subject, and that is this: The male partner may be suffering with a sterility due to an obstructive epididymitis from a gonorrheal infection contracted years ago. During the course of marital life the wife suffers a mild gonorrheal infection, which may in turn be the causative factor of the sterility in her, the development of the fibroids in her uterus being incidental and not necessarily the cause of the sterility. In one case of sterility and fibroids one cause may be operative while in other cases the causes may be several. In one case the cause may be a purely mechanical one, while in the other the cause may be a physiologic one. Until we shall be able to tell what the cause of fibroid formation is we shall not be able to formulate an opinion as to the relation of fibroids and sterility.

Sterility and fibroids are certainly closely associated, and this close association must necessarily be assumed to exist when it is considered that fibromyomatous tumors are associated with the periods of sexual activity. As Haultain[6] says: "Their growth is practically confined to the years between puberty and menopause, and it is doubtful if they ever originate before or after this period; indeed, if uncomplicated by secondary changes, they cease to grow after the climacteric."

There are no reliable statistics available of large numbers of cases to show what proportion of fruitful women are subject to myomatous growths of the uterus, to indicate how statistics of that character would compare with fibroids in single and sterile women. The subject of fibroids and their relation to sterility under consideration consists really of two parts; one is the subject of sterility itself and the other is fibroids of the uterus. Sterility by itself is a complex subject, little understood, and the same is true of the cause of fibroids.

From a clinical point of view there is a practical side to this question of sterility and fibroids and the manner of behavior of the myomatous tumors toward the pregnant uterus. Clinical experience has shown that the pregnant uterus, under certain conditions, is tolerant toward the fibroid growth. In these clinically favorable cases neither the pregnant organ itself nor the progress of the pregnancy is in any way harmfully affected by the growths in the uterus. With this evidence at hand we certainly are permitted to infer that fibroids of the uterus, under certain not clearly understood conditions, are not harmful to the pregnancy, to the fetus or to the patient herself. This being the case, we can deduce the practical lesson not to disturb myomatous growths during pregnancy unless there is clinical evidence at hand to show that the pregnant organ has become intolerant to the tumors in its walls. The size of the growth, or its situation, does not necessarily determine the tolerance or intolerance of the pregnant organ toward the tumors, but the size and situation are of great moment, so far as the future labor is concerned. The size of the tumor, and its situation as well, become important factors at the time of the labor on account of the possibilities of the tumor causing difficulties during the delivery in the form of mechanical obstruction.

Right here a practical question may be asked. What type of tumors should be attacked surgically during pregnancy? The teaching is that a tumor should be removed if pedunculated, excessively movable, greatly enlarged, or so situated as to cause mechanical obstruction during the coming labor. Surgical procedures are justifiable under these conditions even if the uterus is tolerant to the tumor in its walls. Pedunculated fibroids are removed because they are subject to twisting during pregnancy; they are also subject to degeneration during the process of subinvolution of the uterus.

To judge properly what fibroids will cause mechanical obstruction during labor is a difficult task. Cases are on record in which competent observers considered the situation of the tumors dangerous and undoubtedly liable to cause obstruction during labor, but in which under the test of labor the patients delivered themselves spontaneously or with the aid of low forceps operation. We must be constantly on guard in giving positive opinions on this question of obstructed labor by low-implanted fibroid tumors of the uterus. These low-implanted tumors become lifted out of the true pelvis during the progressive enlargement of the uterus, during the pregnancy, and when labor sets in very little if any mechanical obstruction is encountered.

[6] Haultain: In Allbutt and Playfair's System of Gynecology, p. 562.

What is the present teaching as regards the so-called interstitial fibroids and operative interventions during pregnancy? Clinical histories have established the fact that interstitial fibroids are of the type of tumors that cause miscarriages most frequently, and yet tumors of this type, when enucleated during operation, will cause the greatest number of abortions, because the pregnant organ suffers the greatest amount of traumatism during the removal of these deep-seated tumors. In view of these facts it becomes an important question what is best for a physician to do when called on to manage these cases. Each case of this type must be treated on its own merits. If the pregnant uterus seems intolerant to the presence of the tumor, which should be shown by periodic more or less severe uterine contractions, then an operation should be seriously considered, because with symptoms so marked a miscarriage is impending and a myomectomy may jeopardize the pregnancy to a less extent than the persistent uterine contraction.

The submucous fibroids are the type of tumors that cause sterility most frequently. This sterility is due not so much to the tumors themselves as to the congestion to the mucous membrane of the uterus, which their presence engenders and maintains. Once conception occurs in uteri with submucous fibroids the surgical attitude toward these tumors in pregnancy is the same as in the interstitial type of fibroids.

In the multiple fibroids of the uterus pregnancy has proved to be a dangerous complication. Clinical evidences are at hand showing that under those conditions abortions occur frequently, and great difficulty is at times experienced in properly emptying the cavity of the uterus of the product of the conception. Septic infections are frequently encountered in these cases, and gangrene of the tumors is not an infrequent complication, calling for total hysterectomy to save the life of the patient.

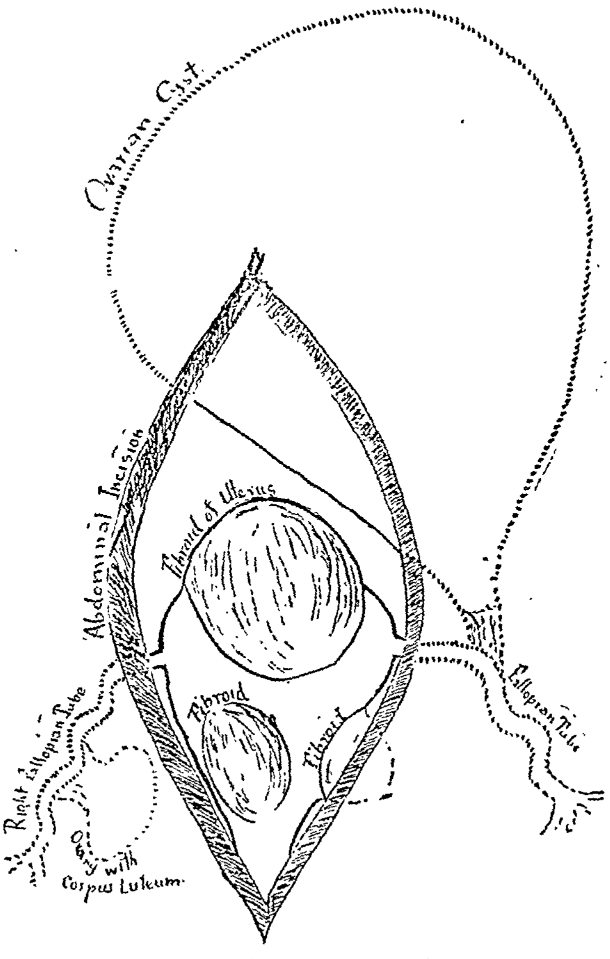
In the case the history of which I shall presently relate several interesting points arose previous to the operation.

1. The patient was suffering with an ovarian cyst which twisted on its pedicle, causing acute symptoms.
2. There were several fibroid nodules to be felt on the uterus.
3. The patient was a primipara, married nine years.
4. She was extremely anxious for a child.
5. For a week or ten days previous to the onset of the acute symptoms the patient had very definite and frequent contraction pains of the uterus, permitting the interpretation of the symptoms that a miscarriage was impending.

When the necessity arose for an operation the question was asked, what would be the best thing to do in this particular case, in view of the definite symptoms present numerated above. Should the offending neoplasm, the twisted ovarian cyst, alone be removed and the fibroids be left undisturbed for fear of inviting a miscarriage, or should the entire surgical field be simultaneously attacked? I felt that in this particular case I had no right to ignore the symptoms that pointed to a tendency on the part of the uterus to empty itself, and so a myomectomy was also performed. The question may be asked, given a case of early pregnancy, with several small fibroids in the uterus that the pregnant organ kindly tolerates, if an ovarian cystoma be present at the same time, whether it would not be good surgery to remove the offending cyst alone and leave the fibroids undisturbed. It seems to me that such a procedure would be perfectly justifiable, since we know that gravid uteri are frequently most tolerant to myomatous growths.

The history of the case is as follows:

CASE 2.—*History.*—Mrs. H., aged 37, was seen on Aug. 9, 1907. She was brought to the hospital in a carriage, having fainted on the street. She was complaining of pain in the abdomen, which came on very suddenly, causing vomiting and fainting, resulting in a collapse on the street. The pain was sharp, cramp-like in character, excruciating at first; it gradually subsided and when I saw her about two hours after the attack her abdomen was simply tender but no pain was present. For a week or ten days before this attack the patient had not been entirely well, having suffered with cramp-like pain in the abdomen, moderate fever, indigestion, and an uncomfortable feeling in the bladder. The cramp-like pain of a bearing-down character, lasting for a short period, would let up only to reappear again at short intervals. She had been married nine years but never had been pregnant; the cause of the sterility was not known. Her menstruation was always normal, of the four-weekly type, moderate in amount, lasting from three to four days. Her last menstruation, on July 28, had been



Fibroids of gravid uterus, and ovarian cyst.

very scanty, almost none. She did not know if she were pregnant or not, having had some slight morning nausea and the scant menstruation at the last period. Family and previous history negative.

Examination.—The general condition of the patient was good. Heart and lungs normal; abdomen was not enlarged but was tender to the touch. Bimanual examination revealed a slightly enlarged uterus with several fibroidal nodules on its surface. A large movable tumor was also present in the pelvis. The diagnosis was ovarian cyst, with twisting of pedicle, fibroid of the uterus and pregnancy. On account of the extreme movability of the pelvic tumor it was thought that the attack of pain was due to the twisting of the tumor on its pedicle.

The patient was advised to submit to an operation for the removal of the tumor and for a myomectomy. The patient and the family were very anxious for offspring.

Operation.—After careful preparation the patient was operated on Aug. 13, 1907. The abdomen was opened in the median line, the pedicle of the cyst was tied off and removed. There were three fibroids in the uterus varying from the size of a walnut to that of a lemon, the larger one of the tumors extending deep into the uterine wall. The tumors were removed by shelling them out of their beds and the uterus was closed with interrupted catgut sutures. In some places the bleeding from the uterine wall was quite free, necessitating very careful suture application. The ovarian tumor was on the left side. The right ovary was enlarged considerably and a corpus luteum of pregnancy was plainly visible. The abdomen was closed in layers and the patient put to bed in a very good condition.

Postoperative History.—The patient regained consciousness with very little, if any, nausea. She vomited a few times. She returned from the operating-room at 10:30 a. m. and at 4:30 p. m. a bright, bloody flow from the vagina was noticed. Morphin was administered hypodermically to relieve pain and to quiet uterine contractions. The patient was allowed to take water freely. Twenty-four hours later the bloody flow had diminished considerably but it was still bright red in color. Fifty-two hours later all bloody discharge had stopped. The bowels moved thirty-six hours after the operation. Some vaginal discharge reappeared again but this was from some blood that remained in the vagina, as it disappeared on administration of a douche. The abdominal wound healed by first intention; an entirely afebrile recovery took place. The patient sat up in two weeks and left the hospital in the fourth week. Two months after the operation the patient removed to Canada, where she placed herself under the care of a physician, who wrote to me that the patient was making a very satisfactory progress with her pregnancy and no abnormal or untoward symptoms had appeared as a result of the operation. On April 4, 1908, she was delivered of a nine-pound baby. Her labor pains started at 5 p. m. and the baby was born with forceps at 11 p. m. In other words, it was practically a normal delivery.

159 West One Hundred and Twentieth Street.

ABSTRACT OF DISCUSSION

Dr. Howard A. Kelly, Baltimore: We are very much at variance in different parts of the country or even in the cities in regard to methods. I am glad that Dr. Grad spoke of the growing tendency to non-interference. I am constantly sending these patients back home without doing that which was expected when they came to me. When the tumor is in the upper part of the pelvis I habitually leave it alone, unless it is producing marked symptoms, and I do not recall any case now within some years that has been producing symptoms requiring interference. I am glad also that he referred to the fact that there were tumors which though low down might get high enough up not to obstruct delivery. When a tumor is low down it is a good practice to put the patient under a little gentle anesthetic and see if it can be pushed up. The chances are then favorable for delivery at term. Even when it is down in the cervical portion the patient may go to term, although when the tumor is large I do not think it is wise to wait for delivery *per vias naturales*. I have had a case of this kind within a year; a large, stout woman was delivered with great difficulty of a large child which lived. Shortly after she was sent to me with an enormous tumor blocking the cervix. Had she come to me at the end of pregnancy and I had found that tumor there I would have said that delivery was impossible. Yet the tumor was slipped up and with great difficulty and with considerable risk to life the child was born. In a case like that of Dr. Grad I would have opened the abdomen and taken out the tumor. I have a number of myomectomies in pregnancy to my credit, successful ones, but I prefer not to interfere, but to let them alone and to wait.

Dr. Henry D. Fry, Washington, D. C.: Dr. Grad has spoken of these tumors which are frequently low down in the pelvis during pregnancy and as a result of pregnancy, the growth of the uterus and contractions of the muscular fibers are drawn up out of the pelvic cavity so that delivery through the natural passages would be possible. When there is a pedicle the tumor can be pushed up, but even in the interstitial form of fibroid, low down blocking the pelvis, I have seen them frequently rise up in the later months of gestation and get above the brim and the woman give birth to her child naturally. On two occasions I have had to do a Porro operation when the fibroid was projecting down in the vagina and when on examination it seemed as if the fetal head were in the pelvis. There was a large round solid mass projecting down and when I operated I thought that I would have to do a panhysterectomy but I found the cervix was pushed away up above the symphysis pubes that the tumor had grown down from behind by a pedicle and was blocking the passage. One danger of leaving these fibroids alone, even when high up in the uterine wall, is the occurrence of suppuration after childbirth. I have had three cases of this kind. One patient was sent to me by Reynolds of Boston, five months pregnant. I intended to let her go until near term and do a Porro operation. However labor commenced unexpectedly with strong pains. When I reached the house the cervix was dilated to the size of a silver half dollar. She was brought to my hospital as quickly as possible. The pains continued until there was almost complete dilatation of the cervix. The labor had progressed so far that I had abandoned the plan of the Porro operation and permitted her to have her child by the natural passages. She did well for five or six days. She then went into collapse, had a high fever and was not in condition at any time afterward when I could do an operation. I knew that necrosis had occurred but she was in such a desperate condition I did not dare to operate. Autopsy showed a fibroid much suppurated. There had been rupture into the peritoneal cavity with suppurative peritonitis. In another case I did a hysterectomy, the woman recovered, and in cutting on the fibroid I found a large abscess. In another patient sent in very recently the tumor was not large. At about the eighth month of pregnancy she had a discharge with a disagreeable odor, and labor pains set in followed by premature delivery of an infant. After delivery I saw her at about the fifth day. She still had this discharge and was in bad condition. Her pulse was 32, very weak and she had septic fever. At the fundus of the uterus could be felt the suppurating necrotic fibroid projecting down from the fundus in the cavity of the uterus. She was in too desperate a condition for operation and we let her alone, watching and stimulating her and she recovered. So I think that when we decide to let these women with fibroids have their babies we must watch them very carefully during the puerperium and on the first sign of fever which we suspect is due to suppuration in the tumor we must operate at once.

Dr. A. E. Benjamin, Minneapolis: It has been my experience to have a number of these cases degenerate during the time they were in interstitial stage. In one patient sent to me after delivery I found the fibroid so wedged down and adherent that it was almost impossible to get that growth out of the pelvis. I never worked so hard in any case to get the tumor out. Another patient was a physician's wife who had had three miscarriages. She came to me at the sixth month of pregnancy and was beginning to have pain and some fever. She was in bed. I told the husband that she should be operated on. I enucleated a fibroid the size of a lemon about half way down the fundus of the uterus. She had a living child born in due time. Examination showed the tumor to be diseased in the center. This has been the case with a number examined. I feel that a certain percentage of these patients should be operated on. By careful manipulation operating on the growth itself, it is not necessary to produce abortion.

Dr. J. H. Carstens, Detroit: There are many sides to this subject. Last fall I reported cases that I had collected from all over the world—about 550—and if you look those cases over you will find the mortality is very low and that the operative mortality during pregnancy is not greater than in women not pregnant. All these patients were operated on by abdominal section without any trouble. These women could not be delivered otherwise. I have seen women who died undelivered. I had one patient, in whom I had to remove the uterus containing any number of fibroid tumors, who was delivered normally. The fibroids and the uterus were contracted so firmly, however, that it was impossible to deliver the placenta which became decomposed and the woman was septic in the highest degree and I had to operate on her four days after delivery. All these cases occur and it seems to me we can not lay down any definite rule. If a woman is pregnant and has a fibroid or any kind of tumor I think she is in a serious condition and her mental condition is not of the quietest. So we ought to consider seriously whether such patients should be operated on or not. I think a good many require operation during pregnancy and will stand it just as well as at any other time without producing abortion. In these 550 cases it was perfectly astonishing how many women went to full term after myomectomy. These records from all over the world have convinced me that myomectomy during pregnancy is not a serious operation and that furthermore nearly all the women will go to term and will save their children just as well.

Dr. H. Grad, New York City: In this case myomectomy was done because the patient presented definite symptoms of uterine intolerance toward the fibroids in its walls. She had uterine contractions which were very painful and on that account myomectomy was done after the ovarian cyst was removed. Had she had no symptoms I think I would have been tempted to leave the fibroids, and she probably would have gone on to full term as she did.

THE TRANSMISSION OF BOVINE TUBERCULOSIS TO CHILDREN*

HENRY LARNED KEITH SHAW, M.D.
ALBANY, N. Y.

Theobald Smith in 1896 described certain differences in the virulency, morphology and cultural growth between the tubercle bacilli found in human tuberculosis and in bovine tuberculosis. Koch at once commenced a series of experiments, with the result that he not only confirmed the observations of Smith but went further and announced at the British Congress for Tuberculosis in 1901 the following conclusions:

1. The tubercle bacilli of bovine tuberculosis are different from those of human tuberculosis.
2. Human beings may be infected by bovine tubercle bacilli, but serious diseases from this cause occur very rarely.
3. Preventive measures against tuberculosis should therefore be directed primarily against the propagation of human tubercle bacilli.

Koch has been persistently misquoted and the impression is deeply implanted in the lay and medical mind that he denied absolutely the possibility of human infection from the bovine type of the tubercle bacillus. In order to offset the effect on the general public of such a statement by so eminent an authority several governments appointed commissions to make a thorough investigation. The Royal Commission of England is perhaps one of the most important. The pathologists forming this commission—Woodhead, Martin, Boyce and McFadyean—before their appointment had publicly taken views strongly in favor of the possibility of the frequent transmission of bovine tuberculosis to human beings. It is no secret that they intended and expected to have no difficulty in proving in a short time that Koch was wholly wrong in his position.

They have now been at work over seven years and their conclusions are not much at variance with those advanced by Koch. They find that "there can be no doubt but that a certain number of cases of tuberculosis occurring in the human subject, especially in children, are the direct result of the infection into the human body of the bacilli of the bovine type." They investigated sixty-four cases of human tuberculosis and found the bovine bacilli in only fourteen of these carefully selected cases. Not one of these fourteen were in pulmonary tuberculosis but were from glandular cases.

Ravenel read a paper before the British Congress in 1901 which was diametrically opposed to Koch's views in emphasizing the great frequency of tuberculosis contracted from the ingestion of milk from tuberculous cattle. The same views were reiterated in 1905 and he asserted that the majority of cases of tuberculosis of children were of alimentary origin and due to the bovine bacillus. Last fall, in his public address before the International Congress at Washington, he admitted that only a small but a definite percentage of cases of intestinal tuberculosis in children were of bovine origin.

The situation has recently been summed up by Adami, who says: "The more we have studied the more we have been reducing the number of cases that are of bovine origin and increasing the number of human origin."

It is safe to assert that the scientific world is agreed on the existence of these two types of tubercle bacilli. The technic for their differentiation has been simplified so that the determination can be carried out in any laboratory.

A few investigators, while admitting the existence of these types, believe the differences are due to the host and that the two have a common origin and can revert to the original type after cultural methods and passage through animals. In refutation of this view Theobald Smith says:

> That the bovine type should be converted into the human type has no analogy in the domain of bacteriology and as long as it is not clearly proved to occur, it cannot be accepted on mere speculation. Again, if the bovine and human cultures are indiscriminately transmitted to either species, why should two types have arisen?

This is a question of purely theoretical value in the combat against tuberculosis; for Koch has well said that it is absolutely without significance what changes tubercle bacilli will undergo after being passed through a series of animals or during cultivation under some artificial conditions. Fresh and unchanged tubercle bacilli are taken in the milk and only the morphology of fresh and unchanged bacilli should be considered.

Veranus Moore of Cornell University stated within the past year that between 20 and 36 per cent. of all cattle in the state of New York are affected with tuberculosis.

In Belgium 49 per cent. of the cattle reacted to the tuberculin test and 49.5 per cent. in Denmark. Reports from the slaughter-houses of Prussia showed that 14.6 per cent. of the cattle had macroscopic lesions of tuberculosis and in Great Britain tuberculosis was found in 26 per cent. of the slaughtered cattle. Hess found tubercle bacilli in 16 per cent. of the specimens of milk he examined in New York City. There undoubtedly may be an abundant discharge of tubercle bacilli in the milk when the udder is diseased. It has also been shown that tubercle bacilli are found in the milk of cows in which there are no signs of udder tuberculosis. These, however, are present only in very small numbers. They are found only at intervals because the bacilli after the rupture of some focus do not circulate in the blood for any length of time, but are at once picked up and fixed in the tissues.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

The Canadian government made a series of observations on fifteen cows which had reacted to the tuberculin test and been condemned. Tubercle bacilli were found in the milk of 5, and 88 animals (rabbits and guinea-pigs) were inoculated with this milk and only in 3 instances was any trace of tuberculosis found. Ten calves from healthy non-reacting cows were suckled for seven months on the milk of these tuberculous cows and in no instance did tuberculosis develop. The tuberculous cows were slaughtered and all showed tuberculosis, either of the lungs, intestines or glands, but a careful examination failed to detect any involvement of the udder. If calves, who are so susceptible to the bovine bacilli, were not affected in these tests there is but very slight probability that the human infant would be infected with this milk.

Wysckowych found that it was necessary to have at least fifteen tubercle bacilli injected into the tissues of the guinea-pig to produce infection. This is very different from introducing bacilli into the intestines, for it must be remembered that the contents of the intestines are as much outside the body as are the contents of the nostrils or external ear canal. A child might ingest thousands, or even millions, of bacilli and yet too few enter at any one point through injury or lesion of the intestinal wall to be able to set up tuberculosis. It should also be borne in mind that the bacilli do not multiply in the milk.

Infection to tuberculosis during life takes place through the air (inhalation infection) and from the food (ingestion or alimentary infection). The inhalation infection may take place through the nasopharynx, respiratory or alimentary tracts. Holt and Albrecht found involvement of the lymph nodes and lungs in 99 per cent. of their autopsies on cases of tuberculosis in children. In the home of a tuberculous adult the dangers to the child are enormous. Miller, in a study of 150 children whose parents were under treatment for tuberculosis, found physical signs of tuberculosis in 51 per cent.

Infection through the intestinal tract may come from human bacilli coughed up and swallowed; toys, fingers, food, etc., contaminated with human bacilli; or food, especially milk, containing bovine bacilli.

Bovaird, who has given special attention to the frequency of primary intestinal tuberculosis, concludes that it occurs among children in this country in about 2 per cent. of all cases of tuberculosis, while in Great Britain it is found in 18 per cent. Albrecht of Vienna found only 7 cases of primary intestinal tuberculosis in 3,213 autopsies, of which 1,060 showed signs of tuberculosis. Comby, in his series of 1,447 autopsies on children showing tuberculosis, did not find a single case of primary intestinal tuberculosis. He also makes the assertion that in his private practice among dispensary and hospital patients during twenty-five years of practice he has never seen a case of tuberculosis in a child contracted through the milk. He points out that tuberculous cattle have been largely exterminated in the dairies supplying Paris with milk and that milk in its raw state is very rarely used for infant-feeding, yet these stringent prophylactic measures against bovine tuberculosis have not had the slightest effect on the mortality of tuberculosis in children. Holt says: "Infection through the intestinal canal by means of tuberculous milk I believe to be a very infrequent means of acquiring tuberculosis in infancy."

Kitasato and Shiga have recently written interesting articles on tuberculosis in Japan; they show that human tuberculosis is as frequent in Japan as in the civilized countries of Europe and America. They also state that intestinal tuberculosis is relatively common in children although cow's milk is never used and plays no rôle at all in the feeding of children. Avison, a medical missionary in Korea, found tuberculosis very common and yet the natives never touch cow's milk or give it to their children. Responsible observers in other portions of the globe have reported similar conditions.

Harlow Brooks' account of the eradication of tuberculosis among the monkeys in the New York Zoo is significant. For years the mortality from tuberculosis was a great source of expense, as about 50 per cent. died from this disease. In making the autopsies Brooks was struck by the similarity of the tuberculous lesions in monkeys and children. A thorough disinfection of the cages was made and the healthy and diseased monkeys separated. Every new monkey was given a careful physical examination and kept in quarantine for several weeks. Tuberculosis was eliminated in the course of two years and the mortality reduced to nil. The food and milk was not changed, so the contagion must have come through the sputum or direct contact, not from the milk.

Infectious diseases are not infrequently found confined to the route of one milkman. There is no instance on record in which it has been pointed out that many of the children along one route have shown intestinal or general tuberculosis, although it is quite probable that the majority if not all the cows supplying the milk may have advanced udder tuberculosis.

Passage of the bacilli through the intestinal walls and mesenteric lymph glands into the thoracic duct and thence deposited in the lungs is the explanation of some excellent pathologists of the infrequency of intestinal tuberculosis.

Cornet made over 3,000 animal experiments and formulated the law that wherever tubercle bacilli are introduced into the body they produce either a localized tuberculosis or involve the regional lymph glands surrounding the area of infection. It is hard to understand on the basis of these experiments how the bovine bacilli could pass through the mesenteric glands without producing any changes in the tissues and then set up tuberculosis in remote organs. Albrecht, in his large series of autopsies, finds that the Cornet law applies invariably to the source of infection in children and he denies the possibility of the infection entering the circulation through the intestinal tract without leaving any trace in the mesenteric lymph glands. Holt acknowledges the possibility of the bacilli entering the digestive tract without producing intestinal lesions and setting up a lung or bronchial gland infection, but he asserts that this is not the usual course or the natural interpretation of the conditions found at postmortem examination. Theobald Smith calls attention to the fact that the tubercle bacilli are living organisms which arouse a more or less prompt reaction on the part of the invading tissues, and that they can not travel about the body at will without being recognized and held.

Bovine tubercle bacilli have never been detected in the sputum of tuberculous patients. At a private conference at the International Congress at Washington Koch asked about fifty of the leading pathologists and bacteriologists of the world if they could quote any case in which bovine bacilli had been surely isolated from human cases of pulmonary tuberculosis. One such case was cited, but the possibility of contamination had not been fully guarded against, so that it can be stated that up to the present time no authentic case of pulmonary tuberculosis in man due to the bovine type of tubercle bacilli has been reported. The natural conclusion from this is of great value, as statistics show that fully eleven-twelfths of deaths from tuberculosis are from the pulmonary variety and only one-twelfth from all other forms of the disease. A number of pathologists have found bovine bacilli in tuberculous glands. Theobald Smith isolated bovine bacilli in twelve out of twenty-eight tuberculous cervical lymph glands removed by operation and in one case of tuberculous meningitis. Hess examined mesenteric glands from three cases of primary intestinal tuberculosis in children, but found the human type in all three cases. He has found the bovine type of tubercle bacilli in excised tonsils. Hamilton White examined a series of tonsils removed from children and inoculated them in guinea-pigs. Some of the pigs died from septicemia, but of the 50 pigs inoculated not one showed tuberculosis of either type. The English and German commissions have also found bovine bacilli in tuberculous lymph glands. Theobald Smith, from his personal investigation and study of the literature, believes that "between 1 and 2 per cent. of all cases of tuberculosis will show bovine bacilli and that in individuals over twelve years of age they will be found only very rarely."

I have reported an instance in which a strong chain of circumstantial evidence convicted a cow of transmitting fatal tuberculosis to a fourteen-months-old infant. Organs from the infant were sent to the Pathological Laboratory at Harvard, where the bacilli were found to be of the human type. The cow was slaughtered and no trace of tuberculosis could be found, although she was said to have reacted positively to the tuberculin test. Kerley has reported several instances in which all appearances were against the cow but on bacteriologic investigation the lesions were found to be due to the human type of tubercle bacillus.

A circular letter of inquiry regarding the possibility of bovine transmission was sent to the members of the American Pediatric Society and leading pathologists. Thirty-seven believed it possible, although ten of these qualified their replies by stating that transmission occurred "in relatively rare cases," "exceptionally," "to a very limited extent," etc. Five replied in the negative, while twenty-five would express no opinion. Only three of the thirty-seven who believed in the transmission of bovine tuberculosis could report positive cases in which the infection came clearly from the milk and the bacilli proved to be of bovine origin.

The question is far from settled. Professor Adami of Montreal recently stated that "at first Koch went to one side too much and his opponents went to the other side too much, but at present the truth seems to have come nearer Koch's view than the other view."

The secular press is well supplied with sensational articles magnifying the great damage of bovine tuberculosis. This campaign of newspaper advertising will result in a wide-spread belief among the laity (and unfortunately some members of our own profession) that bovine infection is the principal cause of tuberculosis in man. As a natural sequence the public would feel it could disregard the ordinary rules of sanitation and hygiene provided the possibility of infection through milk could be eliminated by pasteurization of milk and slaughter of tuberculous cattle.

Dr. Bensel of the New York City Board of Health has said that he "deprecated the spread of alarm in the mind of the public as regards the danger of tuberculosis from milk."

Koch declared at Washington that in order to decide this important question he was going to undertake experiments on a broad scale during the next two years. This great problem is so vital that it should be dealt with in a temperate and scientific manner.

In a previous communication on this subject I have stated that tuberculous cattle are a menace to public health and give the disease through their milk in rare instances. Efforts to stamp out the disease in cattle should be made, but the attention of the public should not be diverted from the great and very real danger of human contagion. Whether this takes place through the respiratory or digestive tract is immaterial.

In view of the practical bearing of this question from a sanitary, hygienic, and dietetic point of view and the evident confusion and lack of positive knowledge, this Section should take up a systematic study of bovine tuberculosis and its transmission through milk. A committee could be formed to make a report at each meeting of the work that is being done in different countries and to urge and see that a differential bacteriologic examination be made in all suspected cases, not alone of intestinal involvement, but of the bronchial glands, lungs, and tonsils. State laboratories and pathologic laboratories of medical colleges would gladly aid in such an investigation.

198 Washington Avenue.

ABSTRACT OF DISCUSSION

Dr. William H. Park, New York: It is now accepted by nearly every one that Koch went too far, in virtually excluding bovine infection as a source of tuberculosis in man. The British reports may lead to conclusions too far the other way. If this is so, it is only because their material was selected from one locality. The men who did the work are of such ability and standing that a charge of bias hardly deserves consideration. Undoubtedly there are some who believe that nearly all tuberculosis comes through milk, but most of us are convinced that human tuberculosis, in the great majority of cases, is due to human infection. If we are to determine through bacteriologic findings the source of infection, it must first be established that the human and bovine types of health have persistent and clear-cut differences. We have sufficient facts to enable us to state definitely that cultures obtained from infants under a year, show their original characteristics so that when we find a distinct bovine or human type we can say definitely that this infection is from a human or a bovine source.

With a number of bacteriologists in the New York Department of Health, I have been testing the characteristics of the tubercle bacilli in a large number of cases. We are trying to get a fair quantitative opinion by taking all the cases of tuberculosis in these children's hospitals. We have examined additionally cultures from 200 adults and they have all been of the human type. So far we have finished our tests of the cultures from 70 children. These comprised 35 cases of generalized tuberculosis and an equal number in which the disease was localized largely in the lymph glands, bones or joints. Of the 35 suffering from generalized tuberculosis, 6 were due to the bovine type of the bacillus; 4 of these 6 bovine cultures came from 8 children obtained from one hospital. None of these was fed on breast milk. Of the other 29, only 2 were of the bovine type. Of the 35 cases of general infection in infants, there were 10 in which meningeal symptoms were pronounced and all were due to the human type.

One history is interesting: A little child who had been started on certified milk, after the third month was given commercial milk. A little later this child developed abdominal tuberculosis, and was operated on unsuccessfully. The bacilli were found to be of the bovine type. Two samples of the milk when injected produced tuberculosis. Several of the cows on the farm showed advanced tuberculosis, but no other tuberculosis was detected.

Of the surgical cases, there were 29 of involved lymph nodes. Of these 20 were due to the human type and 9 to the bovine type. Of the 5 cases in which a joint was involved all were human. In one patient with abdominal tuberculosis, operated on with recovery, the bacillus was bovine. Altogether 23 per cent. of all the cases among young children were due to the bovine type and 17 per cent. of the fatal cases. I judge that about 1.5 per cent. of all cases of fatal tuberculosis in New York City is due to bovine infection. That would mean at least 200 deaths. Of course 200 or 300 deaths are not many when contrasted with the total number, and yet if they occurred from any other disease it would be considered a very important matter. I believe we can take measures to prevent this type of infection without interfering with the far more important work of controlling the spread of infection from man. In the course of a few years we will have definite results from the investigations now being carried out in many centers of population and the relative importance of bovine and human bacilli in human infection will thus soon be finally settled for the whole civilized world.

Dr. Alfred F. Hess, New York: I don't believe that Professor Koch is misjudged in his statements. He said that bovine tuberculosis was very rare and that it did not require more consideration than the congenital type. Dr. Shaw has shown that is not correct. If these types of human and bovine tuberculosis interchange, then we have made but little progress; but I do not believe that it has been definitely shown that these types do interchange. It is difficult to get at this question because we do not know the time of the bovine infection; we are almost never able to say when the infection took place. Recently I had occasion to examine two cases of butchers' tuberculosis in slaughter-house employés. One had been infected four years ago and in the other the infection had occurred six years ago. In both cases I injected a guinea-pig and in both cases the bacillus was typically bovine and had not assumed the human type. Again, if the bacillus does not change in the human tissue, we ought occasionally to find the bovine bacillus in early pulmonary cases before this hypothetical change has taken place; whereas it has been shown that a bovine case of pulmonary tuberculosis has not been recorded. As to the small percentage being important, 1 per cent. does not seem large, but when you recall that the yearly mortality in the United States from tuberculosis is about 200,000, then certainly 1 per cent. mounts up to thousands of cases. If these cases were classed as foot-and-mouth disease, it would certainly be regarded as important enough to require even Federal consideration.

Dr. S. McC. Hamill, Philadelphia: If it has been demonstrated, as it has by Dr. Park's statistics, that as many as 300 deaths occurred from bovine tuberculosis in children under 5 years of age in one year in New York City, then the number of deaths in children from this cause in the entire United States must represent a very high figure. I think the men investigating the incidence of bovine tuberculosis have done it in a fair-minded way. The attitude of those who have opposed Professor Koch has been not to demonstrate bovine infection, the sole or chief type of infection, but to prove that bovine tuberculosis is not a negligible quantity and that it represents an important percentage of the cases which occur in early life and that it is the duty of those directing the health of communities to protect the public from the possibility of this form of infection.

Dr. H. L. K. Shaw, Albany: I did not mean to criticize the British investigators. They were very fair. Dr. Park's figures correspond exactly with those of Theobald Smith. I do not want to belittle the question of bovine tuberculosis, but the New York State Board of Health can not get more than $7,500 to fight human tuberculosis, and my aim was to emphasize the importance of the fight against human infection.

EMBOLOMYCOTIC ANEURISMS *

DEAN LEWIS, M.D., and V. L. SCHRAGER, M.D.
CHICAGO

Aneurisms developing during the course of endocarditis and occasionally during some of the acute infectious diseases form a distinct group. The frequent involvement of the visceral arteries and the latency of clinical course probably accounts for the relatively small number which have been noted *in vivo*, most of the cases having been discovered accidentally during routine post-mortem examinations. These aneurisms differ in pathogenesis, clinical course, and prognosis from those developing secondary to chronic arterial changes. Enough isolated cases have now been reported to warrant a critical examination of the clinical histories with the view of obtaining data relative to the diagnosis and the lines of treatment to be followed in cases of this type.

Rokitansky[1] as early as 1844 recognized and described true abscesses in the walls of arteries, the sequence of the lodgment of infected emboli.

The first description of an embolomycotic aneurism was apparently made by Koch[2] in 1851. Koch's patient was a young man, 22 years of age. He was being treated for endocarditis, when, without any previous abdominal symptoms, he suddenly died with all the manifestations of intra-abdominal hemorrhage. The autopsy revealed vegetations on the mitral valve and a ruptured aneurism of the superior mesenteric artery. A little later than this English clinicians and pathologists described a series of cases and recognized the relationship existing between embolism and aneurism formation.

ETIOLOGY

In 1853 Tufnell[3] reported an aneurism of the popliteal artery in a young man, aged 25. In the history of this case it is stated that there were "cauliflower-like excrescences" on the aortic valves.

Thirteen years later Oggle[4] stated that there was a definite relationship between aneurisms in young people and verrucous endocarditis. Church,[5] Goodhart,[6] Barlow and other English observers were of the opinion that many aneurisms in young people were of embolic origin.

Ponfick[7] and Eppinger[8] were the first, however, to make careful anatomic examinations of aneurisms of this type. The former found in one of the early cases of aneurism of the cerebral vessels studied by him a pointed, calcified embolus projecting through the arterial wall into the cavity of the false aneurism. He suggested a purely mechanical causation and believed three things necessary for the development of an aneurism of this type: (1) a calcified, pointed, barbed embolus; (2) lodgment of the embolus at the bifurcation of a vessel; (3) loose connective tissue surrounding the vessel, and not resistant tissue which could afford some support to the arterial wall. He cites in support of the third requirement that embolomycotic aneurisms do not occur in the renal vessels, although pointed, calcified emboli must lodge there, while they are relatively common in the vessels of the loose cellular tissues about the spleen and in the mesentery, and still more common in the vessels of the soft brain tissue.

This traumatic or mechanical explanation did not suffice for all aneurisms of this type, for cases were frequently found in which a soft embolus was found at the site of beginning aneurism formation. Eppinger, employing reliable bacteriologic technic, could establish a direct relationship between the embolus at the site of aneurism formation and the endocardial vegetations, as he could demonstrate similar bacteria in each. He believed that, as the result of lodgment of an infected embolus, an exudative periarteritis and later a mesarteritis developed, that a part of the elastic and muscular elements were destroyed by bacteria and their toxins, and that the remaining parts of the media and adventitia were forced outward to form the sac of the aneurism. He suggested that the term "embolomycotic," embracing both the embolic and infectious nature of the lesion, be applied to aneurisms of this type.[9]

The suggestion that an aneurism might follow the lodgment of a benign embolus, the dilatation being due to the sudden increase of pressure proximal to the point at which the embolus lodged, cannot be accepted. If aneurisms could be caused in this way, they would certainly develop frequently after the ligation of vessels, and this practically never occurs unless infection develops at or proximal to the point of ligation.

We believe, after an examination of the literature and of the cases herewith reported, that this type of aneurism may develop in one of three ways. Most commonly they follow an endarteritis associated with lodgment of infected emboli at the bifurcation of arteries. The process, beginning in the intima, reaches the membrana elastica interna, which is destroyed by the infection permitting of either a localized or generalized distention of the arterial wall. Extensive destruction of the elastic fibers was easily demonstrated in the brachial artery examined by us by Weigert's stain. The observations made by Ponfick and Thoma[10] of calcified emboli in the arterial wall and projecting into the aneurism demonstrate the possibility of traumatic origin. Gambaroff[11] suggests the lodgment of either an infected or bacterial embolus within the media, the embolus passing in through the vasa vasorum. An aneurism developing after the lodgment of the embolus in the media would probably be of the dissecting type.

A few cases of aneurism have been reported which developed during the course of infectious diseases, unaccompanied by endocardial changes. E. Ruge reports an aneurism of a coronary artery in a boy, aged 12, which developed during suppurative osteomyelitis, and Cathcart[12] an aneurism of the femoral artery during typhoid fever. Streptococci were found in the wall of the aneurism in the case observed by Ruge. Cases such as these and those in which the aneurism develops in the course of an artery, rather than at the bifurcation, suggest other etiologic factors. Some of the aneurisms which are regarded as of embolic origin may be due to the arterial changes which have been described by Wiesel[13] during infectious diseases in which embolism can be excluded. As a result of his studies Wiesel comes to the following conclusions:

> 1. During the course of various infectious diseases well-defined pathologic changes occur in the arteries. These, at first limited to the media and in the majority of cases confined to it, consist of degeneration of the musculature and of the elastic fibers. Degeneration occurs in foci, which may be quite numerous in the separate vessels, and leads in severe cases to an actual necrosis of the vessel wall. Healing may occur by scar formation or *restitutio ad integrum*. If the process extends to the intima, cicatricial changes occur and the vessel is permanently damaged. In advanced cases the changes may be recognized macroscopically.
>
> 2. The changes affect all arteries up to a certain caliber (about that of a digital artery), the distribution of foci varying from case to case, the aorta, cerebral and cardiac vessels being, however, most frequently involved.
>
> 3. The cases may be separated into two groups: those associated with especially marked involvement of the elastic elements as in diphtheria, typhoid fever, influenza and pneumonia, and those with most marked changes in the media, as in scarlet fever and septicopyemia.

This work has been cited in detail to show the frequency of arterial changes in infectious diseases. It is quite possible that some of the aneurisms in these diseases have followed these changes, which apparently bear no relation to embolism.

Clinically, embolomycotic aneurisms differ from those following chronic arterial changes: (1) In developing at an earlier age; (2) in frequently being multiple; acute and chronic forms often occurring in the same individual; (3) in the frequent involvement of visceral arteries; and (4) in the tendency to remain small.

It is often difficult to determine the etiologic factors in aneurism in the young. A number of cases are reported in which no satisfactory explanation is given as to the cause. Congenital aneurisms, described by Kussmaul and Meyer and ascribed by Eppinger to an inherent weakness of the arterial wall, are considered by Romberg to be of infective origin. Astley Cooper observed an aneurism of the anterior tibial artery in a boy aged 11, and is responsible for the statement that Mr. Clive had ligated the same artery in a boy (age not stated) for an aneurism which had existed in the upper part of the foot for two years. Cooper is reported to have said that he had been told of two instances of aneurism in children, one involving the carotid, the other the popliteal artery. A definite etiology was not given for these cases. Keen[14] describes a brachial and thoracic aneurism in a girl aged 18 without any heart changes, and also describes one of one of the interosseous vessels of the hand in a young girl. The last was probably of traumatic origin.

[9] The possibility of the embolic origin of aneurisms has been recognized by veterinarians for a long time. These aneurisms are relatively common in horses, the anterior mesenteric artery being most commonly involved and the *Strongylus armatus* being found in the sac. Such cases have been described by Bollinger and are mentioned in the ordinary text-books of veterinary medicine.

In 1903 Le Boutillier[15] published an article dealing with aneurism occurring in early life. He collected reports of 60 cases, 17 of which involved the thoracic and 6 the abdominal aorta. The remaining 37 involved vessels other than the aorta. In 7 of the cases in which the aorta was involved there was either a recent endocarditis or thickened plaques on the valves. Similar conditions were found in 11 of the 37 cases in which vessels other than the aorta were involved.

Table 1 demonstrates the frequent occurrence of *embolomycotic aneurisms in those who are relatively young.* The age of 57 of the 65 patients, including the cases observed by us, have been mentioned.

TABLE 1.—AGES AT WHICH EMBOLOMYÇOTIC ANEURISMS OCCUR

Age.	No. Cases.	Age.	No. Cases.
1 to 10	6	31 to 40	9
11 to 20	15	41 to 50	4
21 to 30	22	51 to 60	1
			57

About one-third of the cases which have been observed developed during the third decade, and about one-fourth during the second. This is in marked contrast to the age at which aneurisms secondary to chronic arterial changes are most common.

The *direct relationship between endocardial changes and aneurisms in the young is positively demonstrated* by these statistics, and we have to conclude that the most important factor in aneurism formation in the young is endocarditis, trauma being the next.

These aneurisms are much more common in the male than in the female. The sex has been mentioned in 57 cases, 41 patients being males, 16 females. In the 14 cases of endocarditis recently studied by Rosenow, 6 patients were males and 8 females. The great preponderance of males afflicted with embolomycotic aneurism suggests the possibility of some determining factors in the development of this type of aneurism. We have attempted to determine whether or not there might be some factors which would favor the lodgment of emboli or favor aneurism formation in the male, but the histories have not been complete enough in most cases to enable us to draw any conclusions as to the blood pressure or chronic renal changes.

We have collected, including the cases observed by us, reports of 97 aneurisms of this type. They occurred in 65 patients, the aneurisms frequently being multiple. The average age of 57 patients (the age of 8 not being mentioned) is about 23 years. The age of the youngest *patient is 5 years, that of the oldest 53.*

LEWIS AND SCHRAGER'S CASES

The clinical course of aneurisms of this type is well illustrated by the cases observed by us, abstracts of the histories of which follow:

Case 1.—*Patient.*—M. Q., a Swede, aged 43 years, was admitted to Dr. Sippy's service at the Presbyterian Hospital April 3, 1908. He had had four distinct attacks of acute, articular rhuematism. Venereal diseases were denied. For several years he had suffered with precordial pain and palpitation of the heart. The symptoms had recently become so severe that he was obliged to quit work.

Examination.—When the patient entered the hospital he complained of precordial pain, palpitation of the heart, and general weakness. He was fairly well nourished; there was some puffiness of the eyelids and some anemia. The pupils reacted to light and accommodation. Eye-grounds were negative, vision good. The nasopharynx and lungs were negative. Cardiac dulness extended half an inch beyond the left mammary line. Auscultation revealed a presystolic murmur, a snappy first tone and a diastolic rumbling at the apex which was transmitted upward.

Course of Disease.—May 20, 1908: Patient complained of a sharp pain in the left hypochondrium associated with a rise of temperature. The left kidney became tender and the urine contained a large number of red blood corpuscles.

May 31, 1908: Patient had a severe chill, accompanied by a rise of temperature, the left kidney becoming tender. Temperature dropped to normal, June 1.

June 2, 1908: Slight rise of temperature and a sudden, violent pain in the left antecubital fossa.

June 21, 1908: A distinct aneurism, the size of a goose-egg, had formed in the left antecubital fossa at the bifurcation of the brachial artery. The aneurism had developed to this size in nineteen days.

July 12: The aneurism had not increased much in size for about three weeks, but on this date, because of the pain occasioned by it, a proximal ligation of the brachial artery was performed under cocain anesthesia. The pain promptly subsided and in about four weeks the aneurism could be pronounced healed.

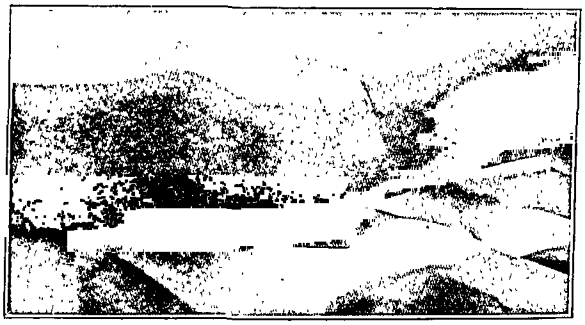

Fig. 1.—Aneurism at bifurcation of brachial artery on day after operation.

August 30: The patient complained of severe pain in the right antecubital fossa. Localized tenderness and some edema developed. The patient frequently complained of pain in the epigastric and hypochondriac regions. These were paroxysmal in character and associated with chills and fever; often followed by blood in the urine. The patient gradually grew worse, became edematous, dyspneic and cyanotic, developed hematuria and hemoptysis, and died Feb. 6, 1909.

Cultures were made at different times from the blood in the aneurismal sac by Dr. E. C. Rosenow. All were sterile. On one occasion, just after a pulmonary infarct, the *pneumococcus was recovered from the general circulation,* but this was the only time. Blood-pressure varied from 140 to 165 mg. of mercury. Before death the site of the aneurism felt like a long, hard connective tissue mass. The radial and ulnar pulses had not returned. Sensation in the hand and temperature of the same were not affected by ligation of the artery.

Autopsy.—This, performed by Dr. Evarts Graham twelve hours after the patient's death, revealed the following: A puckered scar in apex of the left lung; pleural adhesions on the right side; clear fluid in the left pleura; adhesive pericarditis; *calcified vegetations on mitral valve;* enlarged liver with a few scars on the surface. The spleen weighed 780 gm. and was divided into three lobes by bands of connective tissue which ran a quarter of an inch into the splenic tissue. A recent infarct was found in the middle segment. Several scars were found in both kidneys. A recent aneurism, the size of a hickory nut, was found on one of the branches of the superior mesenteric artery. It was a saccular aneurism, the cavity being filled with a laminated clot. The brachial artery at the site of the aneurism was isolated with considerable difficulty from the surrounding tissues, which seemed to form part of it. The brachial artery immediately above and below the point of ligation was patent. Blood-cultures made by Drs. Schrager and Clements after death reveals streptococci and pneumococci.

[14] Keen, W. W.: Two Cases of Aneurisms in Girls of 18 and 8 Years of Age, Med. News, 1887, li, 725.

[15] Le Boutillier, T.: A Case of Aneurism of the Transverse Portion of the Aortic Arch in a Girl Nine Years of Age, with Table of Reported Cases under Twenty Years of Age, Am. Jour. Med. Sc., 1903, cxxv, 778.

As bacteria were not recovered from the aneurism, the entire mass was imbedded in celloidin and sectioned serially with a view of determining whether or not the aneurism was of a traumatic type, due to perforation of the arterial wall by a pointed, calcified embolus, similar to the endocardial vegetations. Every fifth section was mounted and studied, but no embolus was found. The dilated lumen of the vessel involved was closed by a thrombus, which had become detached from the intima during the process of imbedding and cutting. The arterial wall showed marked changes. The intima was practically destroyed; the elastic fibers of the membrana elastica interna took the stain poorly and were broken up into groups. Bundles of fibers of the media were separated from each other by groups of leucocytes and small, round cells, the histologic picture sugesting that the aneurism might have been of the dissecting variety.

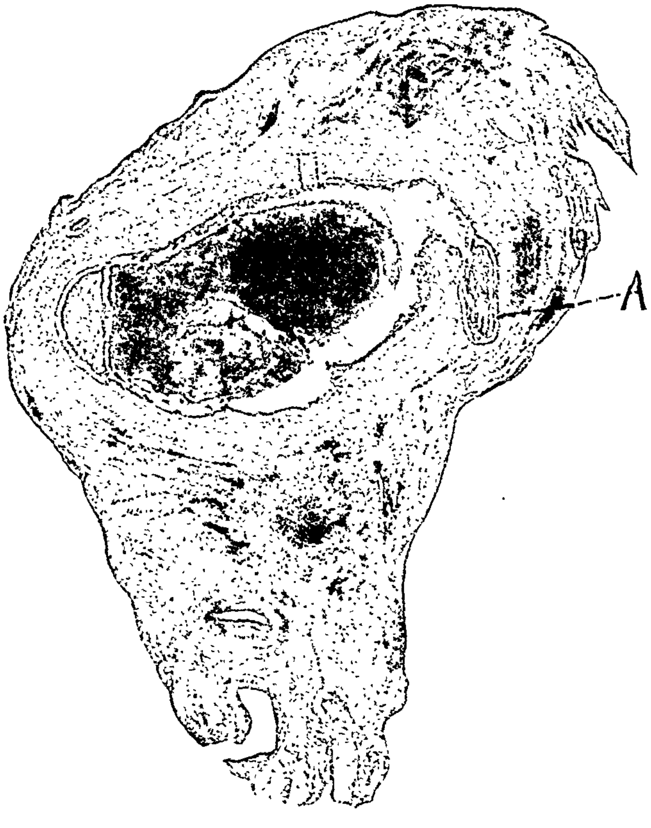

Fig. 2.—Cross-section of brachial aneurism seven months after ligation. A indicates point at which rupture of the arterial wall occurred.

CASE 2.—*Patient.*—A young man, aged 21, was admitted to Dr. Billings' service at the Presbyterian Hospital, April 23, 1908. He gave a history of several attacks of acute articular rheumatism. Two weeks before admission to the hospital he complained of sudden, severe pain just above the left hip-joint. A swelling in which the patient stated that he had noticed pulsation soon developed at the site of the pain.

Examination.—The swelling, situated above and to the outer side of the left trochanter, was as large as a medium-sized grapefruit. It had an expansile pulsation, and a distinct thrill and bruit could be elicited over it. Pulses in popliteal vessels were equal and of the same frequency. Physical examination of the heart revealed the following: Apex-beat fifth interspace just inside the nipple line; no thrill; dulness extended 1 cm. to left of mammary line, to the right sternal border, and above to the third rib. A distinct, loud diastolic murmur was heard over the aortic area and along sternum downward, but this was not transmitted along the vessels of the neck and was heard but faintly at the apex. Capillary pulse present in fingers. Regular water-hammer pulse.

Course of Disease.—May 12, 1908: Needle introduced into the swelling revealed bright red blood. Blood obtained at depth of 3 cm. under pressure. Cultures from this blood positive, a Gram-positive diplococcus in chains of 6, 8 and 10 being isolated. The diplococcus grew well on blood-agar, plain agar, Loeffler's blood serum and in bouillon.

May 29, 1908: The character of the swelling had changed. It had become more extensive and decidedly boggy. It had extended upward, and just below the crest of the ilium there was a marked tenderness. Evidently the aneurism had ruptured.

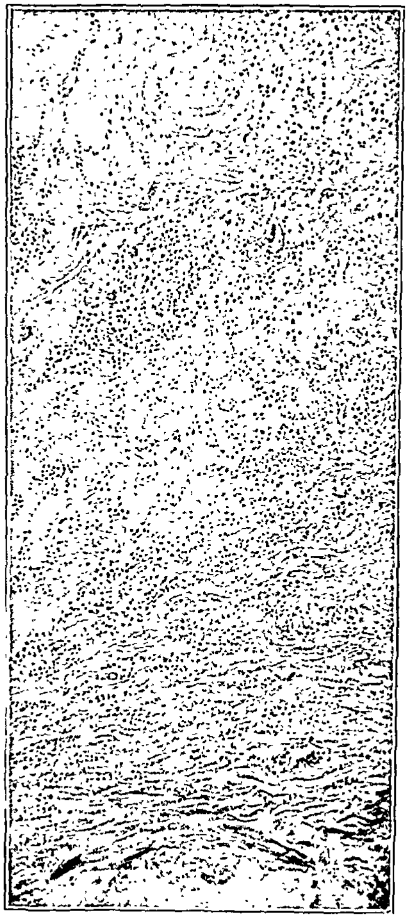

Fig. 3.—Cross-section through wall of artery, showing the bundles of the media separated by groups of leucocytes and small round cells.

June 16, 1908: A soft, pulsating mass, the size of a walnut, developed under the left jaw. No distinct fluctuation.

July 19, 1908: Patient suddenly developed a right-sided hemiplegia, became comatose and died. An autopsy was not permitted, but the clinical findings were definite enough to warrant a diagnosis of aneurism of the gluteal artery.

CASE 3.—*Patient.*—A man, aged 36; no previous history of rheumatism. Five months previous to the beginning of present illness the first lower molar tooth on the right side ulcerated. The tooth was crowned, but the crown had to be removed one month later to let out the pus. It was soon replaced, no trouble developing until one week before death. On Jan. 23, 1909, patient consulted Dr. Slaymaker, complaining of soreness of the throat, running of nose, severe muscular pains, backache and prostration. A probable diagnosis of influenza was made, but the patient grew worse. He entered the Presbyterian Hospital four days later.

Examination.—The spleen was palpable, but there was no agglutination of typhoid bacilli by the serum. No heart murmur detected. The leucocyte count was 7,950 (four days later 12,380), hemoglobin 76. No malarial parasites. Urine negative.

Course of Disease.—On Feb. 19, 1908, there was severe pain over kidneys and right side posteriorly, requiring morphin for relief. Urine, previously normal, now contained albumin and a large amount of pus, many leucocytes, granular and blood casts. There were numerous small petechial hemorrhages beneath the skin. A distinct systolic murmur transmitted to the left was heard at the apex. From this time on the patient failed rapidly, the clinical picture being that of a severe infection. Three days before death he developed a left hemiplegia. The petechiæ became so numerous that a large part of the body was covered by them; conjunctival hemorrhages were also present.

Two blood cultures during life and cultures after death revealed a staphylococcus.

Anatomic Diagnosis.—Alveolar abscess, acute mitral ulcerative endocarditis, embolomycotic aneurism of the superior mesenteric artery, thrombosis of the splenic vein, multiple infarcts of the spleen and kidneys, cloudy swelling and fatty degeneration of the liver, myocardium and kidneys; icterus, anemia and emaciation; multiple hemorrhages of skin, conjunctivæ, serous and mucous membranes, endocardium, myocardium, adrenals and kidneys, hyperplasia of the mesenteric lymph nodes and spleen; lobular pneumonia; emphysema of the lungs.[16]

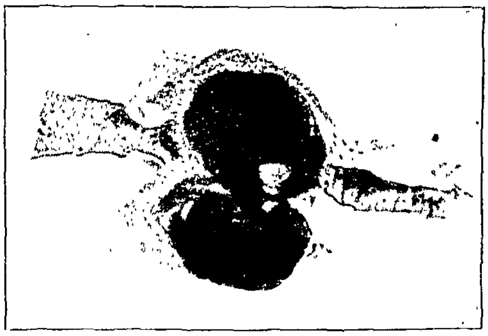

Fig. 4.—Aneurism of superior mesenteric artery discovered at autopsy held on patient seven months after ligation of brachial artery.

DISTRIBUTION

The following table, including 92 aneurisms collected from the literature and the 5 observed by us, demonstrates well the frequency with which visceral vessels are involved.

TABLE 2.—RELATIVE FREQUENCY WITH WHICH THE DIFFERENT VESSELS ARE AFFECTED

Superior mesenteric	25	Internal carotid	1
Cerebral	22	Subclavian	1
Aorta	12	Axillary	1
Femoral	9	Radial	1
Brachial	8	Innominate	1
Splenic	5	Vertebral	1
Popliteal	2	External iliac	1
Ulnar	2	Renal	1
Gluteal	2		
Common iliac	2		97

The following cases are cited to show the number of aneurisms that have been observed in a single patient. In one of Libman's[17] cases there were four aneurisms of the superior mesenteric artery, a fifth on the right branch of the hepatic artery, and a sixth on the right femoral. Before death, the patient developed hemiplegia with aphasia, probably due to rupture of an aneurism of the left Sylvian artery. In the case reported by McCrae,[18] there were five distinct aneurisms of the ascending aorta. In Osler's case there were four aneurisms on the arch of the aorta.[19]

This distribution is in marked contrast to that of the ordinary type of chronic aneurism, as is shown by the statistics compiled by Crisp. Among the 551 aneurisms, reports of which were collected by him, there is not a single instance of involvement of the superior mesenteric artery, and but seven instances of involvement of the cerebral vessels; while aneurisms of the femoral, carotid, subclavian, innominate and axillary arteries are common. Aneurisms of the superior mesenteric artery must be very uncommon, for von Schrötter[20] states that there was but a single instance of aneurism of the superior mesenteric artery among 19,300 cases which came to autopsy at the general hospital in Vienna during a period of ten years.

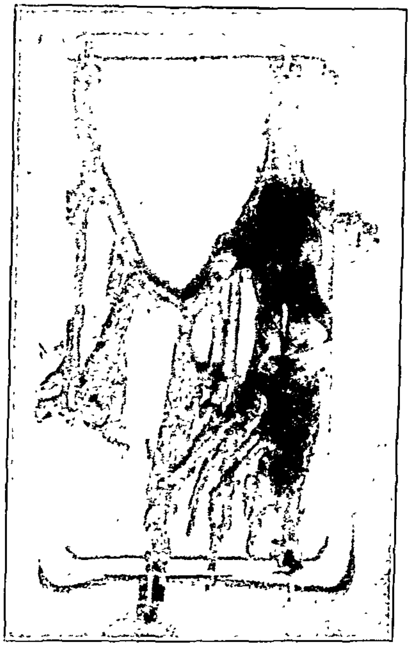

Fig. 5.—Two small aneurisms of the superior mesenteric artery. These aneurisms had caused no symptoms, being discovered during a routine post-mortem examination.

SYMPTOMS

Most of the few cases of aneurism of the superior mesenteric artery that have been published have been of little more than pathologic interest, as they were found during routine post-mortem examinations, and von Schrötter's statement holds true, that these aneurisms give rise to no characteristic symptoms and are usually not suspected until symptoms of fatal intra-abdominal hemorrhage develop.

Gallavardin[21] in 1901 collected reports of 23 cases of aneurism of the superior mesenteric artery from the literature, the etiology of which could be established in 16. Nine of the 16 cases were undoubtedly caused by the lodgment of infected emboli at the points where branches were given off.

---

[16] These two cases have been noted in the anatomic diagnosis of two of the cases studied by E. C. Rosenow: Immunological and Experimental Studies on Pneumococcus and Staphylococcus Endocarditis (Chronic Septic Endocarditis), Jour. Infect. Dis., April 1, 1909, vi, 245.

[21] Gallavardin: Aneurysmes des artères mésentériques, Gaz hebd. de méd. et de chir., 1901, vi, 973.

In analyzing the symptoms presented by aneurisms of the superior mesenteric artery, it is soon discovered that there is nothing characteristic, and that but in few cases has the character of the swelling, which could be palpated, been definite enough to warrant a diagnosis of aneurism. The 2 cases observed by us ran a latent course, nothing developing which suggested aneurism. The patients frequently complained of paroxysms of abdominal pain, indefinitely localized, which we believe was caused by infarction of the spleen and kidneys. Koch's case, the first reported, presented no symptoms until rupture occurred. Some of the cases have been accompanied by paroxysms of excruciating abdominal pain. Duckworth's patient[22] complained of pain in the region of the navel which was so severe that he could not lie down, and his rest was seriously interfered with. Five days after this pain developed, pulsation could be noted in the region of the navel. In Baccelli's case the pain, coming on in paroxysms, was referred to the epigastrium. Whittier[23] reports an interesting case in which an aneurism of the superior mesenteric artery ruptured, dissecting between the layers of the mesentery until it formed a large hematoma in front of the left kidney. This patient complained frequently of severe abdominal pain, each paroxysm being associated with collapse and an enlargement of the palpable mass in the abdomen. All these symptoms were apparently due to fresh hemorrhage from the aneurism. Abdominal pain referred to the umbilicus was probably the most important clinical feature of the cases observed by Jacobson, Duckworth, Baccelli, Whittier, Rehn (reported by Stern)[24] and Gabriel.[25] In 4 of these cases (Duckworth, Baccelli, Rehn and Gabriel) a mass situated close to the navel, usually a little to the right and below, could be palpated. In the case reported by Whittier, mentioned above, the mass which followed rupture of the aneurism developed in front of the left kidney and dissected downward toward the left iliac fossa. In 2 of the cases (Duckworth, Baccelli), the swelling pulsated, the pulsations being characteristic enough to warrant a diagnosis of aneurism.

In but 2 of the cases collected by Gallavardin were there pressure symptoms. In the case reported by Wilson the aneurism compressed the common bile duct, causing jaundice, while in the case observed by Burney Yeo, the aneurism compressed the renal vessels, uremia presumably developing as a consequence. In none of the cases has there been sufficient interference with the circulation to cause necrosis of the intestinal wall.

While the clinical picture of these aneurisms is not characteristic, severe epigastric pain, associated with the development of a mass to the right of and below the navel, in a patient suffering with endocarditis should always arouse suspicion of an aneurism of the superior mesenteric. Unless a definite expansile pulsation were present, usually not the case, it would be impossible to exclude metastatic abscess of mesenteric lymph nodes.

Aneurisms of this type never become very large. The aneurisms of the superior mesenteric artery (Figs. 4 and 5) were about the size of a small hickory-nut, the brachial aneurism the size of a goose-egg. The case reported by Osler, in which one of the aneurisms was as large as a billiard-ball, is probably the largest embolomycotic aneurism observed. The pulsating hematomas formed after rupture of the sac, as in the gluteal aneurism observed by us and in the superior mesenteric aneurism reported by Whittier, became very large, in the latter case filling almost the entire half of the abdomen. These cannot, of course, be included, when speaking of the size of the aneurism.

The fact that these aneurisms tend to remain small or rupture before they attain to any great size accounts for the fact that they cause so few symptoms when situated upon abdominal or cerebral vessels, the symptoms of hemorrhage associated with rupture often being the first indication of the existence of an aneurism.

BACTERIOLOGY

Eppinger was the first to demonstrate bacteria in the wall of the aneurism, and to show the bacteriologic relationship between the vegetations on the heart valves and the clot in the aneurism. He found groups of micrococci occurring singly or in groups, but did not go further in their identification. Buday,[26] in his case, made cover-slip preparations from the endocardial vegetations and thrombus and found in each streptococci, staphylococci and the *Bacillus pyogenes fœtidus.*

Twelve cases have been reported in which a careful bacteriologic examination has been made of blood from the general circulation or from the aneurismal sac. In 6 cases the streptococcus has been isolated, in 5 the staphylococcus. In the case reported by Gabriel streptococci were found in the sac and staphylococci in the circulation. In 1 case the bacillus of influenza was found in the vegetations.

In 2 of the cases observed by us blood cultures made by Dr. E. C. Rosenow revealed the pneumococcus. In 1 of these the cultures were positive but once, and it was impossible to cultivate bacteria from the aneurism, although both streptococci and pneumococci were demonstrated in the blood obtained at autopsy. In the third case staphylococci were isolated from the blood.

Holst[27] reports a case of aortitis with two aneurisms, probably due to the gonococcus, as the lesions developed during a gonorrheal arthritis. It is not stated, however, whether the gonococcus was recovered from the aneurisms or blood.

Patients suffering with aneurisms of this type are apt to be in a critical condition and will not survive a long operation or one associated with much dissection. It must be remembered that the aneurism frequently contains bacteria and that any operation on the tissues adjacent to and composing the aneurism may so reduce their resistance as to cause infection and secondary hemorrhage. The popliteal aneurism observed by Tufnell, one of the earliest cases reported, was evidently cured spontaneously. In Goodhart's case, a brachial aneurism was evidently cured by digital compression applied for seven hours. The patient soon died, however, with the symptoms of cerebral hemorrhage. The brachial artery and, later, the femoral artery were ligated in the case observed by Langton and Bowlby,[28] with good results, but the patient died later of complications associated with endocarditis.

In Canon's case[29] the external iliac artery was ligated for a femoral aneurism, but soon after a brachial aneurism developed, for which proximal ligation was performed, the patient dying ten days later. In one of Libman's cases (a femoral arteriovenous aneurism) the external iliac artery was ligated in two places and divided with the intention of tying the femoral artery below the sac. Resection of the lower end of the sac was attempted, but it was perforated and profuse hemorrhage ensued, necessitating ligation of both the femoral artery and vein. The patient died a few hours later. In another case reported by Libman (operation performed by Lilienthal), the aneurism was incised, the clot removed and the cavity packed. Fifteen days later hemorrhage occurred from the aneurismal sac, which was controlled by packing. Twelve days later the femoral artery was ligated, the hemorrhage having been found to come from a small rupture in the wall of the artery. Six days later the patient died of pneumonia.

[28] Langton, J., and Bowlby, A. A.: Mycotic-Embolic Aneurisms, Brit. Med. Jour., 1882, ii, 1032.

[29] Canon: Bacteriologische Blutbefunde bei Blutvergiftung und Amputation, Mitt. a. d. Grenzgeb. d. Chir. u. Med., 1902, x, 411.

The brachial aneurism observed by us was treated by proximal ligation under cocain anesthesia. Clinically, the result was perfect. The gravity of the prognosis is indicated by the fact that the patient lived but seven months after ligation of the artery, which is the longest time that any patient operated on for an embolomycotic aneurism associated with endocarditis has lived.

Cathcart reports an interesting case of an aneurism of the femoral artery, which developed during typhoid fever. We have classified this as an embolomycotic aneurism, as we believe it to be due to lodgment of bacterial emboli in the vessel wall. He attempted a Matas operation, but the hemorrhage through the recurrent circulation was so severe that the femoral, the deep femoral, the superficial circumflex iliac, the superficial external pudic, the external iliac, the deep epigastric and the deep circumflex iliac arteries all required ligation. Gangrene later developed and an amputation was performed at the junction of the upper with the middle third of the thigh.

In three cases operations have been performed for aneurism of the superior mesenteric artery. In two of these (Libman, Baccelli) the operation has been merely exploratory. In the case reported by Stern (operation by Rehn) the diagnosis of metastatic abscess had been made, but the operation revealed an aneurism of a branch of the superior mesenteric artery. The branch on which the aneurism had developed was ligated and the cavity of the aneurism packed. The patient made a good recovery, but six weeks later another operation was performed for a second aneurism of the superior mesenteric artery. During the operation the abdominal aorta was opened, necessitating ligation. The patient died shortly after leaving the table.

We believe that in aneurisms of this type proximal ligation of the artery is the operation of choice in all cases. Injury of the tissues associated with a Matas operation would favor infection and secondary hemorrhage.

FIELD TRAINING OF MILITIA SURGEONS

FRANK W. HENDLEY, M.D.
Major, Medical Corps, Ohio National Guard
CINCINNATI, OHIO

The thorough systematic training which has been given to officers of the army during recent years, in the various service schools, and by the working out of field problems with troops, has undoubtedly greatly increased the efficiency of the army in all its departments, while the militia, having participated in many field maneuvers, has gained much valuable experience, which is rapidly transforming it into a valuable factor of the national defense.

There are so many things that can be learned only by experience, and so many features which are new, experimental and undetermined, in the modern development of the science of war, that it is only by practice under conditions simulating a war status, that our armies can keep abreast of the progress of the times and maintain the high standards of the past.

Practice under service conditions is as necessary to the various staff departments as to officers and men of the fighting line, and is much more difficult to secure.

While quartermasters and commissaries gain their required practice in all maneuvers, medical officers and the hospital corps have very little opportunity for special training except to a very limited extent, as in maneuvers their services have been required in the actual care of the men of their commands to which they are attached, and there is no time to attend lectures or to execute field problems of medical service appertaining to brigade or division movements.

In the large joint maneuvers the medical department could secure such experience only by the doubling of the present force of medical officers, one set to perform the necessary regimental service with the commands, and the other to carry out the suppositional first aid behind the firing line, with the service of the collecting, dressing and ambulance stations, and the transportation to the rear, etc.

It has been recently pointed out by Major Charles F. Mason,[1] Medical Corps, U. S. Army, that for active service medical officers must constitute 1 per cent., and the hospital corps 10 per cent., of the entire command, and it is evident from our recent experience that a proportion very near to this is necessary in large maneuver exercises, if the medical department is to perform complete service.

It is because of the small strength of the medical corps and the hospital corps that they have been unable to participate in the great benefits derived from maneuvers up to this time.

Their strength is everywhere too small. For example, the Ohio National Guard, with an authorized strength of 575 officers and 7,801 enlisted men, a total of 8,376, authorizes at present 53 medical officers and 236 hospital corps men. (I refer to Ohio simply because the

[1] Mason, C. F.: Seaman Prize Essay, Jour. Mil. Serv. Inst., U. S., January and February, 1909.

statistics in that state are available to me. Possibly the same conditions exist in other states.) Mason shows that the army is far short of its desired quota.

The accompanying list of organizations composing the Ohio National Guard shows the number of medical officers and hospital corps to which they are entitled under "Field Service Regulations."

The entire present force of hospital corps, therefore, is not sufficient to man the two hospitals and two ambulance companies properly, according to regulations, leaving out of consideration entirely all the regiments and other organizations enumerated above.

The desired proportion, according to Mason's estimate, would be still larger, being 83 medical officers and 830 hospital corps men.

If we had the increase to that provided by "Field Service Regulations," we could carry out all the details of the service of the medical department with all troops, not only caring for those actually sick, but simulating also the complete service in the rear of the fighting lines.

In the absence of this desired increase of the personnel, the medical department can do little at a maneuver camp except to operate the regimental infirmaries and to conserve the hygiene of the camp and of the men of the command as far as time will permit.

In order to work out their own field problems pertaining to their own department, their only opportunity will be found in the special "Camps of Instruction for Medical Officers," such as were established this year for the first time, these being separate and distinct from the maneuver camps. To secure the benefit of these camps of instruction requires medical officers to perform two separate tours of camp duty, once with the troops to which they are attached, and again in their own special medical camp of instruction.

The question naturally arises whether it is better to have a small, insufficient force and to use it twice, or to create the proper strength to be used once. In active service the full force is necessary; why not provide it now? Many medical officers of the militia cannot afford the time to attend two separate camps.

The creation of three such camps this year enabled 170 militia medical officers, from forty states, to engage in field work such as they had never been able before to practice, and to attend lectures and demonstrations on every detail of their duties in the camp and in the field, their tour of instruction proving of incalculable benefit to all those who were privileged to attend.

While it is to be regretted that only 170 militia medical officers out of the 700 in the United States attended these schools, and that twenty-five states out of the forty sent only three or less, fourteen sending only one, those who did attend are a unit in expressing their appreciation of the value of the practical instruction received and it can be taken for granted that such schools in the future will be crowded to their capacity.

These schools were held at Antietam, Md., Sparta, Wis., and San Francisco. Those at Antietam and Sparta were in operation four weeks each, instructing two classes each two weeks, that at San Francisco having one class of two weeks.

My personal knowledge relates only to the camp at Sparta during its first course of instruction, July 15 to 28, inclusive. Forty militia medical officers were in attendance, 17 from Indiana, 11 from Ohio, 7 from Michigan, 3 from Illinois, and 1 each from Wisconsin and Mississippi. The camp was located at the western end of a tract of land comprising about 2,700 acres, recently purchased by the federal government for use as an artillery maneuver and target practice camp, about six miles southeast of Sparta, Wis., on the main line of the Chicago, Milwaukee & St. Paul Railway. Three batteries and the headquarters of the Fifth U. S. Artillery were in camp and were engaged in target practice and field work daily during our tour of duty.

Our camp was adjacent to that of the artillery, and for the purpose of our instruction consisted of a complete field hospital of 108 beds, with twelve ambulances, a pack-mule train, and about eighty riding horses. The personnel consisted of ten medical officers of the medical corps, U. S. Army, with about ninety hospital corps men, comprising Company "A," Hospital Corps, from Fort D. A. Russell, Wyoming.

The first day was occupied in arranging quarters, becoming acquainted with each other, and in a critical study of the field hospital arrangements and the details of its management.

On the morning of the 16th the routine work of the school was begun and continued every day without intermission, except on Sundays, to the 28th.

Major T. S. Bratton, Medical Corps, U. S. Army, lectured every day from 8 to 10, making a careful and systematic study of "Army Regulations," the "Manual of the Medical Department," and "Field Service Regulations," as applying to the medical service, considering, in regular order, the laws applying to the organized militia, care of property, accountability and responsibility, duties of post surgeon, the handling of quartermasters' and ordnance property pertaining to the hospital and in possession of hospital corps men, the management of commissary matters, hospital fund, descriptive lists, requisitions, invoices, receipts, hospital charges, savings, rations, record of examinations and assignment to duty, internal economy of hospital, register and record of sick and wounded, sales, purchases, care of property, reports and returns, inspections, muster and pay rolls, discharges, final statements, disability certificates, "line of duty," enlistments, orders, death of soldier, regimental surgeon, regimental hospital, infirmary, ambulance company, field hospital, stationary hospital, brigade surgeon, division surgeon, base hospital, chief surgeon on lines of communication, duties and authority of medical officers, and concluding with the making out of various papers. Major Bratton possessed the faculty of making the subjects interesting and attractive.

Few militia surgeons realize that an intimate knowledge of all these subjects is necessary to them. They study regulations only superficially, if at all, and dread paper-work, the so-called "red tape," simply because they are not acquainted with it. The making of correct records and the proper use of official forms is requisite to the proper protection of the interests of patients under their care, as well as of hospital corps men under their command.

Major W. E. Purviance, Medical Corps, U. S. Army, lectured in the afternoons from 2 to 4 on matters of hygiene and sanitation, both of the camp and of the individual, selection of camp sites, water-supply, cooking, diet, food, drink, bathing, inspections, disposal of wastes, latrines, earth-closets, incinerators, crematories, filters, typhoid fever and other contagious diseases, and physical examination of recruits, with demonstration of such examination. The Conley incinerator, the Lewis and Kitchen incinerator, and the Chamberland and Darnell filters, and the Forbes-Waterhouse water-sterilizer were exhibited in operation and fully explained.

rism developed, for which proximal ligation was performed, the patient dying ten days later. In one of Libman's cases (a femoral arteriovenous aneurism) the external iliac artery was ligated in two places and divided with the intention of tying the femoral artery below the sac. Resection of the lower end of the sac was attempted, but it was perforated and profuse hemorrhage ensued, necessitating ligation of both the femoral artery and vein. The patient died a few hours later. In another case reported by Libman (operation performed by Lilienthal), the aneurism was incised, the clot removed and the cavity packed. Fifteen days later hemorrhage occurred from the aneurismal sac, which was controlled by packing. Twelve days later the femoral artery was ligated, the hemorrhage having been found to come from a small rupture in the wall of the artery. Six days later the patient died of pneumonia.

The brachial aneurism observed by us was treated by proximal ligation under cocain anesthesia. Clinically, the result was perfect. The gravity of the prognosis is indicated by the fact that the patient lived but seven months after ligation of the artery, which is the longest time that any patient operated on for an embolomycotic aneurism associated with endocarditis has lived.

Cathcart reports an interesting case of an aneurism of the femoral artery, which developed during typhoid fever. We have classified this as an embolomycotic aneurism, as we believe it to be due to lodgment of bacterial emboli in the vessel wall. He attempted a Matas operation, but the hemorrhage through the recurrent circulation was so severe that the femoral, the deep femoral, the superficial circumflex iliac, the superficial external pudic, the external iliac, the deep epigastric and the deep circumflex iliac arteries all required ligation. Gangrene later developed and an amputation was performed at the junction of the upper with the middle third of the thigh.

In three cases operations have been performed for aneurism of the superior mesenteric artery. In two of these (Libman, Baccelli) the operation has been merely exploratory. In the case reported by Stern (operation by Rehn) the diagnosis of metastatic abscess had been made, but the operation revealed an aneurism of a branch of the superior mesenteric artery. The branch on which the aneurism had developed was ligated and the cavity of the aneurism packed. The patient made a good recovery, but six weeks later another operation was performed for a second aneurism of the superior mesenteric artery. During the operation the abdominal aorta was opened, necessitating ligation. The patient died shortly after leaving the table.

We believe that in aneurisms of this type proximal ligation of the artery is the operation of choice in all cases. Injury of the tissues associated with a Matas operation would favor infection and secondary hemorrhage.

FIELD TRAINING OF MILITIA SURGEONS

FRANK W. HENDLEY, M.D.
Major, Medical Corps, Ohio National Guard
CINCINNATI, OHIO

The thorough systematic training which has been given to officers of the army during recent years, in the various service schools, and by the working out of field problems with troops, has undoubtedly greatly increased the efficiency of the army in all its departments, while the militia, having participated in many field maneuvers, has gained much valuable experience, which is rapidly transforming it into a valuable factor of the national defense.

There are so many things that can be learned only by experience, and so many features which are new, experimental and undetermined, in the modern development of the science of war, that it is only by practice under conditions simulating a war status, that our armies can keep abreast of the progress of the times and maintain the high standards of the past.

Practice under service conditions is as necessary to the various staff departments as to officers and men of the fighting line, and is much more difficult to secure.

While quartermasters and commissaries gain their required practice in all maneuvers, medical officers and the hospital corps have very little opportunity for special training except to a very limited extent, as in maneuvers their services have been required in the actual care of the men of their commands to which they are attached, and there is no time to attend lectures or to execute field problems of medical service appertaining to brigade or division movements.

In the large joint maneuvers the medical department could secure such experience only by the doubling of the present force of medical officers, one set to perform the necessary regimental service with the commands, and the other to carry out the suppositional first aid behind the firing line, with the service of the collecting, dressing and ambulance stations, and the transportation to the rear, etc.

It has been recently pointed out by Major Charles F. Mason,[1] Medical Corps, U. S. Army, that for active service medical officers must constitute 1 per cent., and the hospital corps 10 per cent., of the entire command, and it is evident from our recent experience that a proportion very near to this is necessary in large maneuver exercises, if the medical department is to perform complete service.

It is because of the small strength of the medical corps and the hospital corps that they have been unable to participate in the great benefits derived from maneuvers up to this time.

Their strength is everywhere too small. For example, the Ohio National Guard, with an authorized strength of 575 officers and 7,801 enlisted men, a total of 8,376, authorizes at present 53 medical officers and 236 hospital corps men. (I refer to Ohio simply because the

[1] Mason, C. F.: Seaman Prize Essay, Jour. Mil. Serv. Inst., U. S., January and February, 1909.

statistics in that state are available to me. Possibly the same conditions exist in other states.) Mason shows that the army is far short of its desired quota.

The accompanying list of organizations composing the Ohio National Guard shows the number of medical officers and hospital corps to which they are entitled under "Field Service Regulations."

The entire present force of hospital corps, therefore, is not sufficient to man the two hospitals and two ambulance companies properly, according to regulations, leaving out of consideration entirely all the regiments and other organizations enumerated above.

The desired proportion, according to Mason's estimate, would be still larger, being 83 medical officers and 830 hospital corps men.

If we had the increase to that provided by "Field Service Regulations," we could carry out all the details of the service of the medical department with all troops, not only caring for those actually sick, but simulating also the complete service in the rear of the fighting lines.

In the absence of this desired increase of the personnel, the medical department can do little at a maneuver camp except to operate the regimental infirmaries and to conserve the hygiene of the camp and of the men of the command as far as time will permit.

In order to work out their own field problems pertaining to their own department, their only opportunity will be found in the special "Camps of Instruction for Medical Officers," such as were established this year for the first time, these being separate and distinct from the maneuver camps. To secure the benefit of these camps of instruction requires medical officers to perform two separate tours of camp duty, once with the troops to which they are attached, and again in their own special medical camp of instruction.

The question naturally arises whether it is better to have a small, insufficient force and to use it twice, or to create the proper strength to be used once. In active service the full force is necessary; why not provide it now? Many medical officers of the militia cannot afford the time to attend two separate camps.

The creation of three such camps this year enabled 170 militia medical officers, from forty states, to engage in field work such as they had never been able before to practice, and to attend lectures and demonstrations on every detail of their duties in the camp and in the field, their tour of instruction proving of incalculable benefit to all those who were privileged to attend.

While it is to be regretted that only 170 militia medical officers out of the 700 in the United States attended these schools, and that twenty-five states out of the forty sent only three or less, fourteen sending only one, those who did attend are a unit in expressing their appreciation of the value of the practical instruction received and it can be taken for granted that such schools in the future will be crowded to their capacity.

These schools were held at Antietam, Md., Sparta, Wis., and San Francisco. Those at Antietam and Sparta were in operation four weeks each, instructing two classes each two weeks, that at San Francisco having one class of two weeks.

My personal knowledge relates only to the camp at Sparta during its first course of instruction, July 15 to 28, inclusive. Forty militia medical officers were in attendance, 17 from Indiana, 11 from Ohio, 7 from Michigan, 3 from Illinois, and 1 each from Wisconsin and Mississippi. The camp was located at the western end of a tract of land comprising about 2,700 acres, recently purchased by the federal government for use as an artillery maneuver and target practice camp, about six miles southeast of Sparta, Wis., on the main line of the Chicago, Milwaukee & St. Paul Railway. Three batteries and the headquarters of the Fifth U. S. Artillery were in camp and were engaged in target practice and field work daily during our tour of duty.

Our camp was adjacent to that of the artillery, and for the purpose of our instruction consisted of a complete field hospital of 108 beds, with twelve ambulances, a pack-mule train, and about eighty riding horses. The personnel consisted of ten medical officers of the medical corps, U. S. Army, with about ninety hospital corps men, comprising Company "A," Hospital Corps, from Fort D. A. Russell, Wyoming.

The first day was occupied in arranging quarters, becoming acquainted with each other, and in a critical study of the field hospital arrangements and the details of its management.

On the morning of the 16th the routine work of the school was begun and continued every day without intermission, except on Sundays, to the 28th.

Major T. S. Bratton, Medical Corps, U. S. Army, lectured every day from 8 to 10, making a careful and systematic study of "Army Regulations," the "Manual of the Medical Department," and "Field Service Regulations," as applying to the medical service, considering, in regular order, the laws applying to the organized militia, care of property, accountability and responsibility, duties of post surgeon, the handling of quartermasters' and ordnance property pertaining to the hospital and in possession of hospital corps men, the management of commissary matters, hospital fund, descriptive lists, requisitions, invoices, receipts, hospital charges, savings, rations, record of examinations and assignment to duty, internal economy of hospital, register and record of sick and wounded, sales, purchases, care of property, reports and returns, inspections, muster and pay rolls, discharges, final statements, disability certificates, "line of duty," enlistments, orders, death of soldier, regimental surgeon, regimental hospital, infirmary, ambulance company, field hospital, stationary hospital, brigade surgeon, division surgeon, base hospital, chief surgeon on lines of communication, duties and authority of medical officers, and concluding with the making out of various papers. Major Bratton possessed the faculty of making the subjects interesting and attractive.

Few militia surgeons realize that an intimate knowledge of all these subjects is necessary to them. They study regulations only superficially, if at all, and dread paper-work, the so-called "red tape," simply because they are not acquainted with it. The making of correct records and the proper use of official forms is requisite to the proper protection of the interests of patients under their care, as well as of hospital corps men under their command.

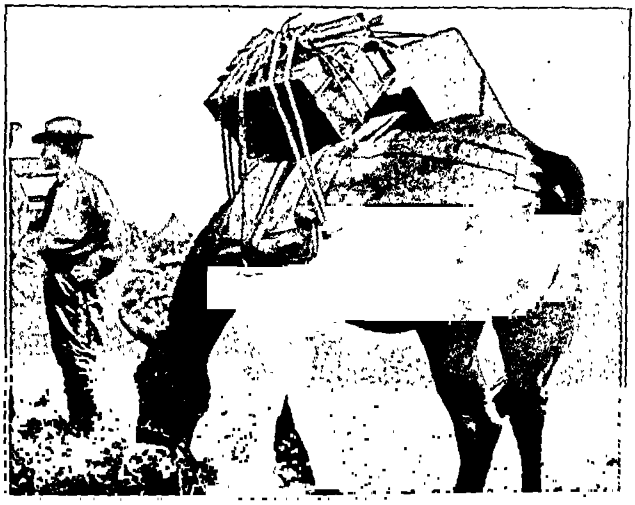
Major W. E. Purviance, Medical Corps, U. S. Army, lectured in the afternoons from 2 to 4 on matters of hygiene and sanitation, both of the camp and of the individual, selection of camp sites, water-supply, cooking, diet, food, drink, bathing, inspections, disposal of wastes, latrines, earth-closets, incinerators, crematories, filters, typhoid fever and other contagious diseases, and physical examination of recruits, with demonstration of such examination. The Conley incinerator, the Lewis and Kitchen incinerator, and the Chamberland and Darnell filters, and the Forbes-Waterhouse water-sterilizer were exhibited in operation and fully explained.

On three days all were engaged in the execution of field problems under the direction of Major P. C. Fauntleroy, Medical Corps, U. S. Army, the commandant.

The first of these, on July 19, was the most extensive, calling for the performance of the work of the medical department of a division of nine regiments, engaged in an attack on the enemy, requiring the establishment of regimental collecting stations, brigade dressing stations, and a division ambulance station, an imaginary field hospital being located in the rear.

The militia officers were assigned as division, brigade and regimental surgeons, mounted hospital corps orderlies furnished; and with the umpires, consisting of the medical officers of the army, and accompanied by ambulances, escort wagon, and a pack-mule train, reached the field of operations after a dusty ride of four miles.

The proper positions being taken in the rear of the division of the army, "Forward" was sounded by trumpet, and all advanced through the woods, fording a stream, and encountering swampy land and almost impassable underbrush, until the cleared land was reached where casualties were to be expected.



U. S. Army pack mule, showing "Arapaho" packed with Varney camp stove, axes, and food chest.

Here the collecting stations were established, following which the dressing stations were located and orders transmitted to the ambulance station to send forward the personnel and equipment for their establishment, which being done, the ground was cleared by chopping down trees to secure space, two tents were erected, an operating table extemporized, beds prepared, instrument cases, medicine chest, and food chest opened in readiness, and a fire started to make coffee and beef-tea.

In the afternoon following this problem a discussion and criticism of the work took place under the direction of Major Fauntleroy, chief umpire, participated in by Capt. C. C. Whitcomb, U. S. Army, and Capt. F. A. Dale, U. S. Army, and various militia officers, in which errors were pointed out, and suggestions made as to improvement of the plan and equipment.

Discussion arose as to whether the ambulance station should not be a brigade unit rather than a division unit, and the opinion was expressed that for carriage on pack-mules the food chest was too large and unwieldy.

The following day (the 20th) all the militia officers were again mounted, and acted as observers in the establishment of a regimental hospital near camp and a dressing station on a hill a mile distant, all the equipment for the complete regulation dressing station, consisting of tent, bedding, medical chest, surgical dressing box, food box, commode chest, stove, buckets, axes, kegs of water, extra litters, etc., being carried on four pack-mules.

Following this the method of packing on pack-mules was exhibited, the construction of the "Arapaho" explained, the method of tying the "diamond hitch" with the lariat, improvised travois constructed, the Varney camp cooker displayed, and instruction given in saddling, mounting and riding horses.

On the 26th field work was again engaged in, the militia officers being assigned as regimental and brigade surgeons, and given details of hospital corps men, with whom search was made through the woods for wounded, represented by tagged hospital corps men, these being given treatment in accordance with the diagnosis on their tags, and removed in ambulances to the camp hospital, where the dressings and extemporized splints were examined and criticized by the umpires, and many valuable suggestions made. It was most interesting to note the ingenuity shown in the treatment of many of these cases.

After this there was hospital corps drill in loading ambulances, carrying by one and two bearers and by litters, and placing wounded men in the saddle.

The regular inspection of the hospital corps, on the 24th, was also studied by the militia officers.

An extremely important element of instruction was derived from observation of the routine operation of the camp, and the actions of officers and men; their careful and exact performance of every detail of sanitary precaution; the constant attention to cleanliness about quarters, kitchens, and at the picket lines; the extreme care given to disposal of wastes and filth; the quiet, orderly and prompt performance of every duty—in short, the magnificent regular army discipline and thoroughness.

As a result of the attention given to sanitation, of course, the camp was free from sickness. All excrement, all urine, and all garbage and refuse being consumed in the incinerators, and all manure dropped at the picket lines being at once removed and burned, it followed that there were very few flies, notwithstanding the fact that in our camp and that of the artillery there was a total of over 400 horses and mules.

Such object-lessons excite admiration and the desire of emulation.

During all lectures, demonstrations, and execution of field problems, the various instructors continually urged the militia officers to ask questions regarding any matters which were not entirely clear, and much valuable data were thus brought out.

All the officers of the army were at all times most courteous, affable, and patient, and the most friendly relations existed.

The foregoing exhibits briefly the extent and scope of the work of instruction provided at this school. The benefits derived from it by all the militia officers who were so fortunate as to participate in the work are enormous and beyond calculation.

The time allotted, two weeks, is all too short for work of such magnitude and variety of detail.

Realizing, however, that few doctors in civil life can afford to devote a longer time to such a camp, in addition to their regular tour of duty with the organizations to which they are attached, I am of the opinion that much of the work done at this camp might profitably be accomplished in a preliminary or preparatory course by correspondence or other satisfactory means, thus leaving the two weeks of camp for the more advanced work, the practical field maneuvers, hospital management, command of men, etc.

A scheme providing a progressive course of training in the preliminary branches of the work, covering six months or more, and requiring a certain degree of proficiency to entitle one to the privilege of attending the two weeks of camp of instruction, should meet with great favor among medical officers of the militia, especially if at the satisfactory conclusion of the entire course some special record of honor was awarded to those who had attained proficiency.

In the absence of such course of training, I would urgently recommend that when another such school of instruction is provided by the War Department every medical officer should be required to attend.

In addition to this, it is imperatively necessary that all medical officers be supplied liberally with the blank forms used by the army, in order that they may become properly acquainted with their use.

Not only do they need each an ample stock of the new cards and other forms of the medical department, but they should have at least a sample set each of many pertaining to the ordnance, commissary, quartermasters, and pay departments—in fact, all that would be required by a company commander or a surgeon in command of a post hospital of the army, as any medical officer is liable to detail at any time to a post where a thorough knowledge of their use is necessary.

RECOMMENDATIONS

1. Medical officers should be increased 50 per cent. and the hospital corps 100 per cent.
2. Training in field service should be provided for the medical corps and the hospital corps.
3. A progressive course of training, covering six months or more, should be provided, to be completed by attendance at a camp school of instruction.
4. Attendance at such school should be permitted only to those who attain proficiency in the preliminary work.
5. The retaining of a commission as a medical officer should be dependent on participation in such systematic course of instruction.
6. Medical officers in states not represented this year should at the next similar opportunity insist on their rights, and not allow their portion of the available fund to be given to their state team at Camp Perry, as occurred in one state in the northwest this year.

Correction of Displacement of Uterus Through Inguinal Canal. Single Incision.—Littauer describes a technic which he has applied in twenty-six cases, with satisfactory and durable results, to shorten the round ligaments by access through the inguinal canal after a single incision through the soft parts. In order to accomplish this the laparotomy incision must be in the form of a curve except in the middle of the fascia which are incised horizontally across; on the sides the fibers of the internus can be easily separated, after which the inguinal canal is readily reached by working down with the finger or a sponge between the external and internal oblique muscles. The round ligaments are then treated as with the ordinary Alexander-Adams operation, the peritoneum sutured, the fascia sutured separately, and the round ligament included in the suturing of the external fascia. His communication in *Sammlung klin. Vorträge* reviews other technics while citing the special advantages of the arc incision in combination with the isolated separation of the fibers of the fascia of the externus for the inguinal celiotomy.

Clinical Notes

A NEW DEVICE FOR DROPPING ETHER AND CHLOROFORM

J. G. ROHRIG, M.D.
IOWA CITY, IOWA

I believe that the device herein described and illustrated meets the need for a small, simple, conveniently portable instrument for dropping ether and chloroform (the former especially) continuously on the inhaler mask, the dose being perfectly and easily regulated, and the rate of drop changed any instant without removing the dropper.

This device is composed of a can (Figs. 1 and 2) with regulating mechanism for outlet, tubes for air inlets, and a screw cap for filling. The can is made in half-pound (250 gm.) and quarter-pound (125 gm.) sizes, which have proved the most convenient ones. At the side of this can, near the top, is an opening for outlet (1 c, Fig. 2). Into this opening extends a cone-shaped valve (2, Fig. 2), which is moved into and out of the opening by the finger by means of a lever (5) so arranged that it is convenient for the forefinger of the hand of the operator to remain on it (at 5 c) continually; thus the operator can at any second change the size of the outlet and thus vary the rate of drop from a strong stream to a slow drop or stop it completely by a mere movement of one finger and without removing the dropper from over the inhaler mask. The can is fitted with a screw cap (7) of large opening so that it can be quickly filled. On the side opposite to the outlet are placed two small tubes (8 and 9, Fig. 2) for the inlet of air. One tube has its external opening at top of can (1 d) and terminates near the bottom of the can on the inside. The second tube enters the bottom of the can (at 1 e, Fig. 2) and opens into the can at its top. This prevents the contents from running out if the can is turned on either end, and also allows the vapor generated by the warmth of the hand to escape by one tube while the outlet is closed without forcing liquid out of the can. The screw (5 b) in the lever is adjustable so that the lever always remains where placed, thereby relieving one from the necessity of holding it continuously if it is so desired. If the small hooks with springs are placed over the air inlets and the lever hook closed, the can may be filled and carried in the instrument bag for days without loss. Thus the dropping can may be filled at the office and carried to a private home ready for use.

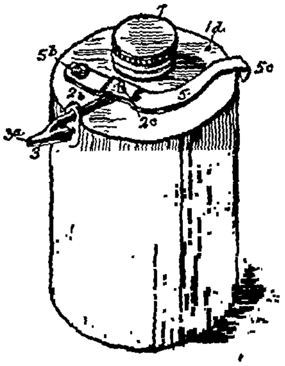

Fig. 1.—Dropper for ether and chloroform.

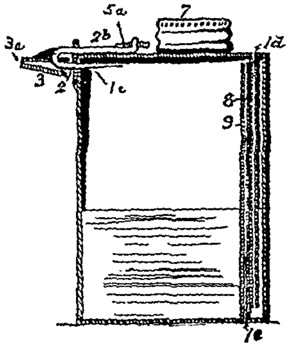

Fig. 2.—Cross-section of dropper.

The can is so arranged that it is conveniently held (Fig. 3). The operator's right elbow rests on the table beside the patient's head and the can is held in *proper* position above the inhaler mask with perfect ease. The rate of drop is properly regulated and the anesthetic is allowed to drop continuously, which is far better and safer than the common method of flooding the inhaler mask at intervals and allowing the liquid to evaporate, the patient breathing pure ether vapor and more or less pure air alternately. This dropping device can be instantly regulated so as to maintain a proper degree of continual anesthesia. When in the beginning the patient vomits, struggles or has a spasm of the glottis, any one of which requires more anesthetic, the finger instantly moves the lever and a proper amount is allowed to fall on the inhaler mask; then the flow may be gradually allowed to return to the proper amount without any extra movements, as of setting the can down, pulling cork, etc.

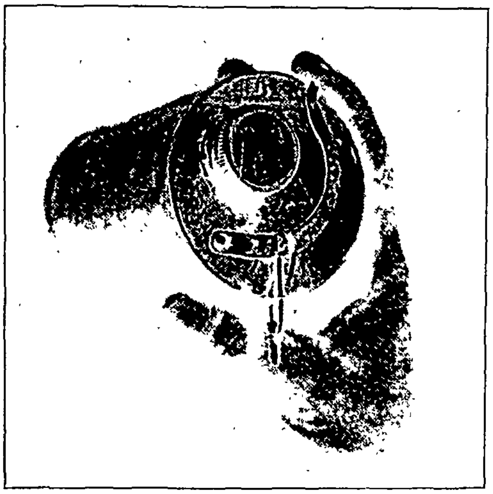

Fig. 3.—Dropper in use.

The claims for this can are as follows:

1. It is safe for the patient because the anesthetic is continuously given and readily regulated.
2. It is small and uncomplicated and, therefore, may be easily carried to a private home or hospital.
3. It is easy to operate, inexpensive, and economical of ether because no excess is poured on at intervals.
4. It drops fast when rapid flow is desired and the flow can be shut down suddenly.

APPARATUS FOR METABOLISM EXPERIMENTS IN MALE INFANTS

FRITZ B. TALBOT, M.D.
Assistant Visiting Physician to Boston Floating Hospital and to the Hospital of the Massachusetts Infants' Asylum
BOSTON

The difficulty of obtaining 24-hour amounts of urine, and the total amount of feces, separately, in babies explains why so few metabolism experiments have been performed during the first year of life. Schabad recently described[1] all the kinds of apparatus which have been used with varying success up to date. The article is very exhaustive and includes his own among other apparatus. These devices are either cumbersome, or difficult to make and procure, and I venture to describe a very simple apparatus which I have used successfully during the past year in collecting the total amount of urine and feces passed by male babies during periods of three days each.

The necessary materials are a small Bradford frame, a towel, two cloth straps each 12 or 14 inches long by 1½ inches wide, safety pins, an ordinary test tube of good glass, zinc oxid surgeons' plaster, and a rubber tube; also a bottle in which to collect the urine, and several wide-mouthed jars in which to collect the feces. The Bradford frame is used because it is easy to handle, and most well-trained nurses are familiar with its use. It is supported on the bed in such a way that it is level and is elevated about six inches above the mattress. The two ends may rest on boxes or rolled-up sheets.

A hole (Fig. 1, A) about three inches in diameter is cut through the cloth of the frame so that it will come under the baby's buttocks; below this the jar in which the feces are collected is placed. A few inches lower down another small hole (Fig. 1, B) about one-half an inch in diameter is cut. The tube through which the urine flows runs through this hole with a gradual but continuous downward incline into a bottle hanging at the side of the bed. The towel (Fig. 1, C) is pinned transversely across the frame with two rows of pins so that the part of the towel attached to the frame is a little narrower than the breadth of the baby's back. The baby is then placed on the towel and the ends are folded over the abdomen and pinned, thus making an abdominal band which extends from the axillæ to just above the groins. This is fastened snugly enough to prevent the body from slipping to either side, and the upper edge is close under the armpits to keep the child from slipping downward.

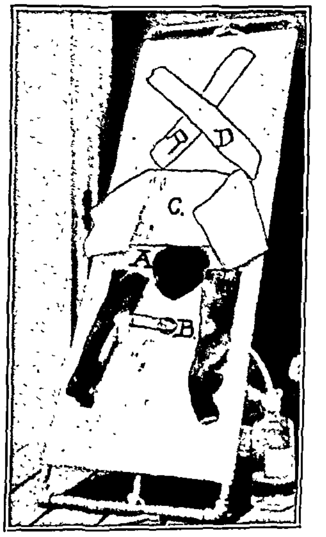

Fig. 1.—General view of the frame used for collecting excreta of male infants. A, hole over which buttocks come; B, small hole through which tube leading from penis is passed; C, towel fastened to frame and which confines the child's trunk; D D, two cloth straps to be pinned transversely across shoulders.

The toes of the stockings are attached to the frame with the legs partially extended, the upper part of the stocking being pinned to the shirt. These stockings are rather loosely knit and act like bags which hold the legs. Two cloth straps (Fig. 1, D) are pinned transversely across the shoulders for greater security in certain cases. The baby is then in a position so that the buttocks remain over the large hole (Fig. 1, A) in the frame, and yet he is not confined enough to prevent a certain amount of exercise, because the legs are only partially restrained and the arms and head can move freely. Babies and children with tuberculosis of the spine are often held in this manner without apparent discomfort for weeks at a time.

---

[1] Arch. f. Kinderheilk., 1908, vol. xlviii, 5-6.

The next problem was to devise a method of collecting the urine. This was done by taking an ordinary test-tube and heating it over a Bunsen burner in such a way that the middle of the tube gradually dropped in; then it was drawn slowly out until shaped as shown in Figure 2. It was then filed at (a), the lower end broken off and the broken edges fire-polished. Such a tube is strong and light and can easily be attached to the penis by straps of surgeons' plaster, while the lower end is connected with a rubber tube leading through the hole (Fig. 1, B) to the urine bottle. Before attaching it the penis should be well covered with boric-acid ointment to prevent maceration of the delicate skin. The bottle should be well washed out with an alcohol solution of thymol to prevent putrefaction.

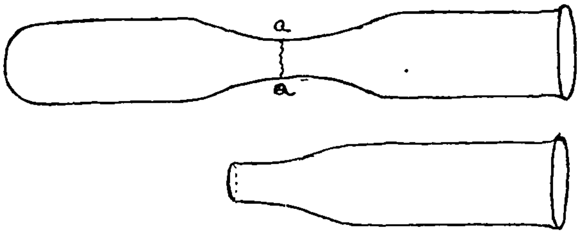

Fig. 2.—Showing method of drawing out heated test-tube so as to encase the penis.

This simple apparatus is very practical because most nurses are familiar with the use of the frame as well as the test-tube. It is light and strong when properly made and there is small chance of losing any of the required excretions. Like all such apparatus, it is open to the criticism that it restricts motion, yet in a small series of selected cases I have seen very little discomfort and no harm from its use.

171 Bay State Road.

UROLOGIC TEST-TUBE HOLDER

G. SHEARMAN PETERKIN, M.D.
SEATTLE, WASH.

This instrument is intended to lessen the difficulties encountered in collecting urine during ureteral catheterization, especially when catheters are retained for long periods, as when testing the functional capacity of each kidney.

Figure 1 shows the holder; the only dimensions noted are those of the opening for receiving test tube, its diameter being ¾ inch. The two projecting prongs are springs; by compressing these, tubes of smaller size may be employed.

Figure 2 shows the test-tube holder in position, and also a metal tent frame (a) constructed of brass, consisting of a center piece 2 inches broad, 24 inches long, and 1/12 inch thick, supported by legs 3/16 inch in diameter and 36 inches from tip to tip, with brass knobs on ends so as not to tear the bed-clothes. The legs being composed of brass, can be easily bent so as to cover persons of varying sizes.

The advantages of this instrument are:

1. When existing pathologic conditions demand general anesthesia, the specimens are not apt to spill nor the catheter to become displaced during the unconscious movements of the patient, and one nurse can readily control the patient if the holders are applied and the knees tied with a broad band of muslin.

2. By additional use of the metal tent frame, the rate, quantity and character of the flow from each catheter can be observed easily by lifting the covers without fear of disturbing the test tube or greatly exposing patient.

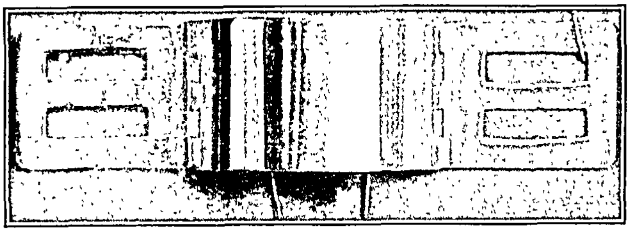

Fig. 1.—Urologic test-tube holder.

3. In employing the test for indigocarmin and phloridizin, the urine must be frequently observed, small quantities taken from receiving receptacle. The ease with which one tube can be substituted for another greatly facilitates this operation.

4. In collecting specimen for microscopic or bacteriologic examination, as in tuberculosis, etc., the possibilities of contamination from outside sources are entirely obviated, since the same centrifuge tube is used to collect as will be employed in centrifugalizing specimen or making culture.

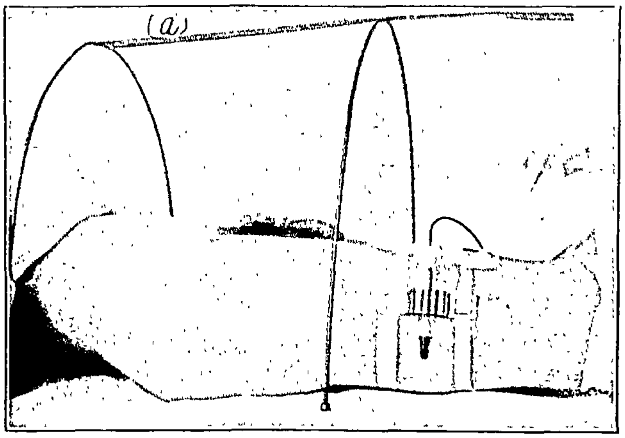

Fig. 2.—Test-tube holder in position; showing also the metal tent frame.

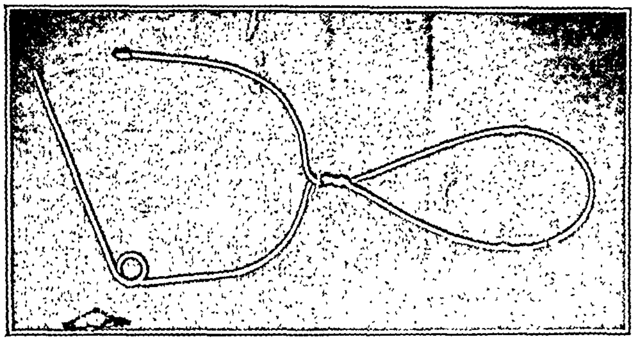
Medical Inspection of Schools in Germany.—Medical inspection and supervision of schools is perhaps more thorough and extensive in Germany than in any other country. Yet even in Germany the system is not complete or uniform. According to the statements of Consul G. N. Ifft (*Public Health Reports*, Oct. 15, 1909), the number of pupils placed under the charge of one physician varies from 1,400 to 22,000, and the salaries from $22.50 to $500 a year. In two cities there are school dentists and in Charlottenburg orthopedic gymnastics are to be given in the schools. The work of the school physician is usually incidental to his general practice. The total pay is determined by the number of classes examined and in Nuremberg amounts on the average to $190 a year. Three examinations of each pupil are required during the first year of school. These are designed to test the fitness of the pupil for the work of the school and consist of a preliminary examination for admission, a second thorough physical examination, and a third in which special attention is directed to the eyes and ears.

A SAFETY-PIN SPRING PROBE RETRACTOR

E. H. THRAILKILL, M.D.
KANSAS CITY, MO.

In the operation for fistula in ano, when the method of excision with the immediate suture is employed, a self-retaining guide is of considerable value, as it renders the services of an assistant unnecessary.

For several months I have been using the simple little instrument here illustrated, which I have found very handy and practical. It is about six inches in length and four inches wide and is made of heavy steel wire, silver-plated. There are no joints or hinges, and the instrument can easily be sterilized.



Safety-pin spring probe retractor.

The method of application is as follows: The probe is released from the hook, passed through the fistulous tract into the rectum, and fastened in the hook again. Then, by taking hold of the handle, the fistulous tract and wall can be firmly held while the diseased tissue is dissected out *in toto*, threaded on the probe.

Owing to the hook and spring resembling those of a safety-pin the name of "the safety-pin spring probe retractor" has been suggested for the appliance. The cheapness, simplicity and effectiveness of the instrument all are points greatly in its favor.

916 East Eighth Street.

A NEW TONSIL KNIFE, WITH GUARD AND RETRACTOR ATTACHMENT *

DANIEL W. LAYMAN, M.D.
INDIANAPOLIS

Dr. Ballenger's clear description of "Tonsillectomy with the Scalpel" and numerous papers by specialists recommending thorough tonsillar enucleation have stimulated men in the use of the knife. This method is advocated as the quickest and most thorough of all procedures. Some of the most skilful users of the knife say that with this instrument the ideal enucleation of the tonsils is accomplished.

Fig. 1.—Tonsil knife, with guard and retractor.

Like many who use the tonsil knife, I have felt the need of something to guard and retract the anterior pillar, without interfering with the movements of the knife, and without necessitating the use of another instrument in the hands of an assistant.

In a great many cases the anterior pillar overlaps a large portion of the anterior surface of the tonsil. Even after freeing this pillar and pulling the tonsil inward with the tonsil forceps, it is often necessary, in using the knife, to retract the anterior pillar with the flat side of the blade to hold it out of the way, in order to dissect the tonsil at the point of attachment. The use of the side of the knife as a retractor not only interferes with the proper dissection of the tonsil, as there must be a constant retracting force exerted on the pillar to keep it out of the way, but also greatly increases the chances of injuring the delicate muscle of the anterior pillar. Hence I have tried to devise a tonsil knife with a pillar retractor and guard attachment.

The retractor and guard attachment is a blunt, flattened hook adjusted to the side of the knife, and having a lengthwise movement parallel with the knife and also a limited movement in the cutting plane. Such movements are made possible by adjusting to a tonsil knife, between base of blade and beginning of handle, an oblong loop or guide, whose plane is at right angles both laterally and transversely with length of knife. This loop, with the shank of the knife, forms two parallel slots through which is passed the retractor, and which not only limits the retractor's movements in the cutting plane, but also steadies it. The shank of the retractor works through the right or left slot of the aforesaid loop, as the operator may place it. The retractor's lengthwise action is controlled by a set-screw. The retractor being slotted, in its long aspect is guided or held by this screw, which engages the knife at that part of the handle nearest to shank of blade.

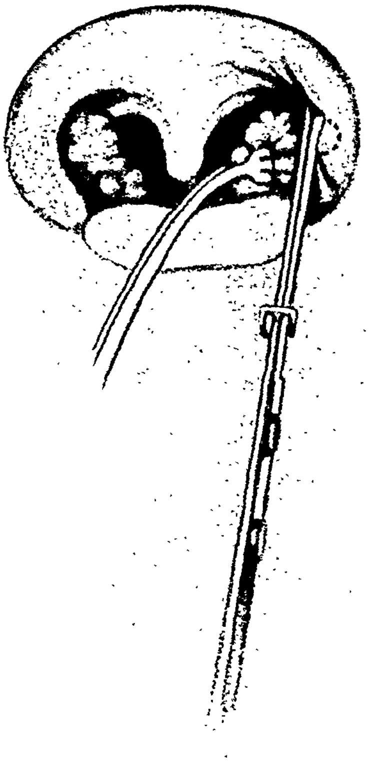


Fig. 2.—Tonsil knife in use.

The knife is best adapted to the sitting posture. The tonsil is first freed from its attachment to the anterior pillar by suitable separators. In most of my cases, after engaging the tonsil with the tonsil forceps, I dissect around the upper half of the tonsil or head, with Kyle's right-angle tonsil knife. In case the plica tonsillaris covers a large portion of the tonsil, I also make an incision at its junction with the anterior pillar. I then regrasp the tonsil, engaging a greater part of the upper part in the tonsil forceps. Then the knife with the guard and retractor attachment comes into play. With the retractor adjusted so that it is freely movable, and the angular blunt hook pulled toward the point of the knife, I insert it behind the pillar.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In cutting downward or upward, as the operator desires, the guard or retractor retains its position, between the tonsil and pillar, as the cutting blade moves forward. Thus the operator can use a great deal of force in retracting the pillar. Besides, the pressure exerted against the pillar by the guard steadies the hand. Especially is this true of the left hand. I never trusted myself with a tonsil knife in the left hand until I used the one with guard and retractor attachment.

This tonsil knife, equipped with guard and retractor attachment, has been used only in a limited number of cases, as the first model was made only last month. The results, however, have been encouraging, and I am convinced that when I use the tonsil knife in the future it will be one equipped with guard and retractor attachment.

My excuse in offering it on such limited experience is that I thought the opportunity presented itself at a meeting where a symposiumon the faucial tonsils was to be one of the chief features. The instrument may be obtained from V. Müeller & Co., Chicago.

Newton-Claypool Building.

A CASE OF PHENOL-POISONING

MONTE STERN, M.D.
SOUTH ST. PAUL, MINN.

S. T., aged 32, Roumanian, was brought into my office in a condition of collapse, with pulse weak and thready, extremities cold, and consciousness almost lost. A cold sweat bathed his body. A hasty examination disclosed burns of the first degree extending from the wrists halfway up both forearms. Vigorous stimulation caused a good reaction from the shock, but within three minutes the patient became very much cyanosed, with labored and stertorous breathing. The respirations at this time went to 56 per minute. The pupils were dilated and reacted very sluggishly to light. The pulse remained strong and was of good volume and tension, but the cyanosis increased to an alarming degree. A slight convulsion manifested itself at this time. More vigorous stimulation was resorted to, with the result that after ten minutes of impending dissolution the patient began to improve. He was now hurried to the hospital, where he remained in a semiconscious condition for three hours, with respirations 26, pulse 80, and temperature 99. Convalescence from this point was uneventful. The urine was cloudy, acid in reaction, brown in color and had a specific gravity of 1.009. Albumin disappeared on the fourth day.

Investigation showed the burns to have been caused by pure phenol applied twenty minutes before the patient was seen. The patient told us that he had applied the phenol to cure a skin eruption and that he felt no pain until five minutes after its application, when the pain became unbearable.

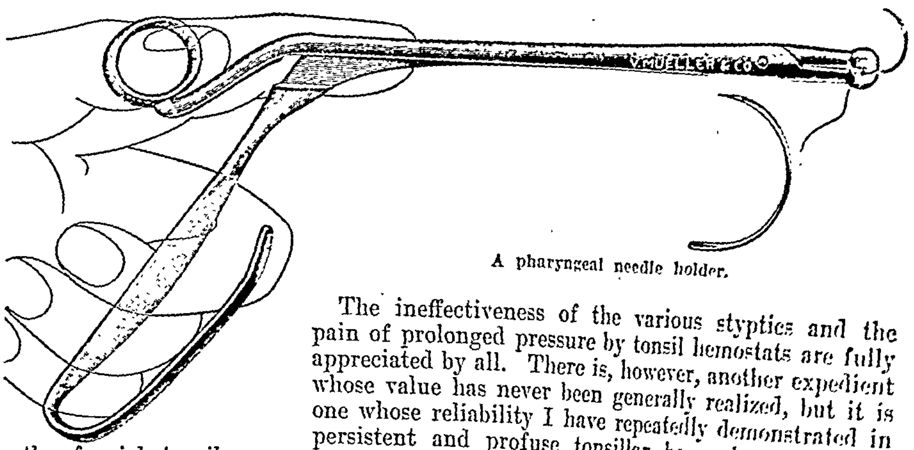
I believe that the primary shock was caused by the pain of the burn and that the condition following was due to the toxic action of the phenol absorbed through the skin.

A NEW PHARYNGEAL NEEDLE HOLDER

DESIGNED ESPECIALLY FOR SUTURING THE TONSILLAR WOUND AFTER TONSILLECTOMY

JOHN O. McREYNOLDS, M.S., M.D., LL.D.
DALLAS, TEXAS

With the substitution of complete tonsillectomy for the simpler but inadequate tonsillotomies of former years there must necessarily develop an increasing danger from postoperative hemorrhage. That the extirpation of the tonsil involves greater responsibility is generally recognized, and we are now concerned with the adoption of such methods as will minimize the risk from hemorrhage.



A pharyngeal needle holder.

The ineffectiveness of the various styptics and the pain of prolonged pressure by tonsil hemostats are fully appreciated by all. There is, however, another expedient whose value has never been generally realized, but it is one whose reliability I have repeatedly demonstrated in persistent and profuse tonsillar hemorrhage after all other methods had been faithfully employed without avail. This consists simply in suturing firmly the tonsillar wound to a sufficient extent to close up all denuded bleeding areas. This may require from one to three sutures, according to the nature of the case, and the stitches may include simply the two pillars of the fauces or they may include within their grasp the tissues at the base of the tonsillar excavation. The suture material which I have found best is a large size of black braided silk. The needles which have proved most satisfactory have been of the Hagedorn variety and of the size and curvature shown in the illustration.

But the factor of by far the greatest importance in the prompt and easy introduction of the sutures is the needle holder. After trying all of the usual forms of needle holders I was led to devise the one here illustrate

The handle must be so placed that the hand of operator is always out of the field of vision. A SAFETY-PIN SPRING PROBE RETRACTOR

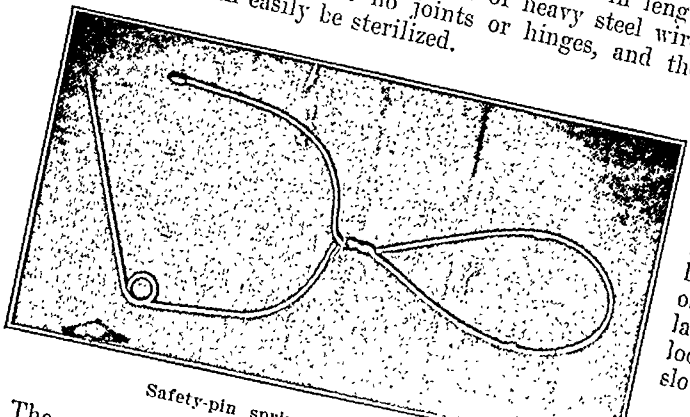
E. H. THRAILKILL, M.D.
KANSAS CITY, MO.

In the operation for fistula in ano, when the method of excision with the immediate suture is employed, a self-retaining guide is of considerable value, as it renders the services of an assistant unnecessary.

For several months I have been using the simple little instrument here illustrated, which I have found very handy and practical. It is about six inches in length and four inches wide and is made of heavy steel wire, silver-plated. There are no joints or hinges, and the instrument can easily be sterilized.



Safety-pin spring probe retractor.

The method of application is as follows: The probe is released from the hook, passed through the fistulous tract into the rectum, and fastened in the hook again. Then, by taking hold of the handle, the fistulous tract and wall can be firmly held while the diseased tissue is dissected out *in toto*, threaded on the probe.

Owing to the hook and spring resembling those of a safety-pin the name of "the safety-pin spring probe retractor" has been suggested for the appliance. The cheapness, simplicity and effectiveness of the instrument all are points greatly in its favor.

916 East Eighth Street.

A NEW TONSIL KNIFE, WITH GUARD AND RETRACTOR ATTACHMENT *

DANIEL W. LAYMAN, M.D.
INDIANAPOLIS

Dr. Ballenger's clear description of "Tonsillectomy with the Scalpel" and numerous papers by specialists recommending thorough tonsillar enucleation have stimulated men in the use of the knife. This method is advocated as the quickest and most thorough of all procedures. Some of the most skilful users of the knife say that with this instrument the ideal enucleation of the tonsils is accomplished.

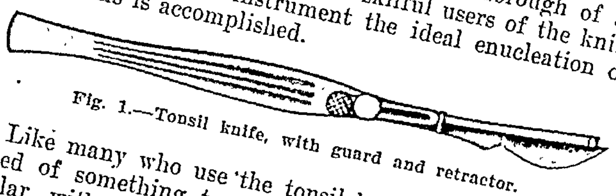


Fig. 1.—Tonsil knife, with guard and retractor.

Like many who use the tonsil knife, I have felt the need of something to guard and retract the anterior pillar, without interfering with the movements of the knife, and without necessitating the use of another instrument in the hands of an assistant.

In a great many cases the anterior pillar overlaps a large portion of the anterior surface of the tonsil. Even after freeing this pillar and pulling the tonsil inward with the tonsil forceps, it is often necessary, in using the knife, to retract the anterior pillar with the flat side of the blade to hold it out of the way, in order to dissect the tonsil at the point of attachment. The use of the side of the knife as a retractor not only interferes with the proper dissection of the tonsil, as there must be a constant retracting force exerted on the pillar to keep it out of the way, but also greatly increases the chances of injuring the delicate muscle of the anterior pillar. Hence I have tried to devise a tonsil knife with a pillar retractor and guard attachment.

The retractor and guard attachment is a blunt, flattened hook adjusted to the side of the knife, and having a lengthwise movement parallel with the knife and also a limited movement in the cutting plane. Such movements are made possible by adjusting to a tonsil knife, between base of blade and beginning of handle, an oblong loop or guide, whose plane is at right angles both laterally and transversely with length of knife. This loop, with the shank of the knife, forms two parallel slots through which is passed the retractor, and which not only limits the retractor's movements in the cutting plane, but also steadies it. The shank of the retractor works through the right or left slot of the aforesaid loop, as the operator may place it. The retractor's lengthwise action is controlled by a set-screw. The retractor being slotted, in its long aspect is guided or held by this screw, which engages the knife at that part of the handle nearest to shank of blade.

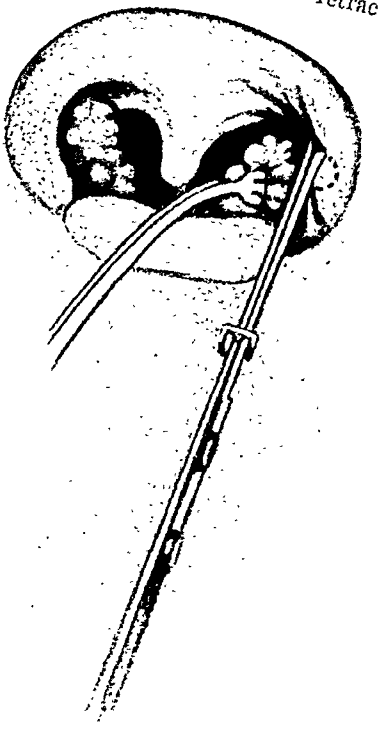

Fig. 2.—Tonsil knife in use.

The knife is best adapted to the sitting posture. The tonsil is first freed from its attachment to the anterior pillar by suitable separators. In most of my cases, after engaging the tonsil with the tonsil forceps, I dissect around the upper half of the tonsil or head, with Kyle's right-angle tonsil knife. In case the plica tonsillaris covers a large portion of the tonsil, I also make an incision at its junction with the anterior pillar. I then regrasp the tonsil, engaging a greater part of the upper part in the tonsil forceps. Then the knife with the guard and retractor attachment comes into play. With the retractor adjusted so that it is freely movable, and the angular blunt hook pulled toward the point of the knife, I insert it behind the pillar.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In cutting downward or upward, as the operator desires, the guard or retractor retains its position, between the tonsil and pillar, as the cutting blade moves forward. Thus the operator can use a great deal of force in retracting the pillar. Besides, the pressure exerted against the pillar by the guard steadies the hand. Especially is this true of the left hand. I never trusted myself with a tonsil knife in the left hand until I used the one with guard and retractor attachment.

This tonsil knife, equipped with guard and retractor attachment, has been used only in a limited number of cases, as the first model was made only last month. The results, however, have been encouraging, and I am convinced that when I use the tonsil knife in the future it will be one equipped with guard and retractor attachment.

My excuse in offering it on such limited experience is that I thought the opportunity presented itself at a meeting where a symposium on the faucial tonsils was to be one of the chief features. The instrument may be obtained from V. Müeller & Co., Chicago.

A CASE OF PHENOL-POISONING

MONTE STERN, M.D.
SOUTH ST. PAUL, MINN.

S. T., aged 32, Roumanian, was brought into my office in a condition of collapse, with pulse weak and thready, extremities cold, and consciousness almost lost. A cold sweat bathed his body. A hasty examination disclosed burns of the first degree extending from the wrists halfway up both forearms. Vigorous stimulation caused a good reaction from the shock, but within three minutes the patient became very much cyanosed, with labored and stertorous breathing. The respirations at this time went to 56 per minute. The pupils were dilated and reacted very sluggishly to light. The pulse remained strong and was of good volume and tension, but the cyanosis increased to an alarming degree. A slight convulsion manifested itself at this time. More vigorous stimulation was resorted to, with the result that after ten minutes of impending dissolution the patient began to improve. He was now hurried to the hospital, where he remained in a semiconscious condition for three hours, with respirations 26, pulse 80, and temperature 99. Convalescence from this point was uneventful. The urine was cloudy, acid in reaction, brown in color and had a specific gravity of 1.009. Albumin disappeared on the fourth day.

Investigation showed the burns to have been caused by pure phenol applied twenty minutes before the patient was seen. The patient told us that he had applied the phenol to cure a skin eruption and that he felt no pain until five minutes after its application, when the pain became unbearable.

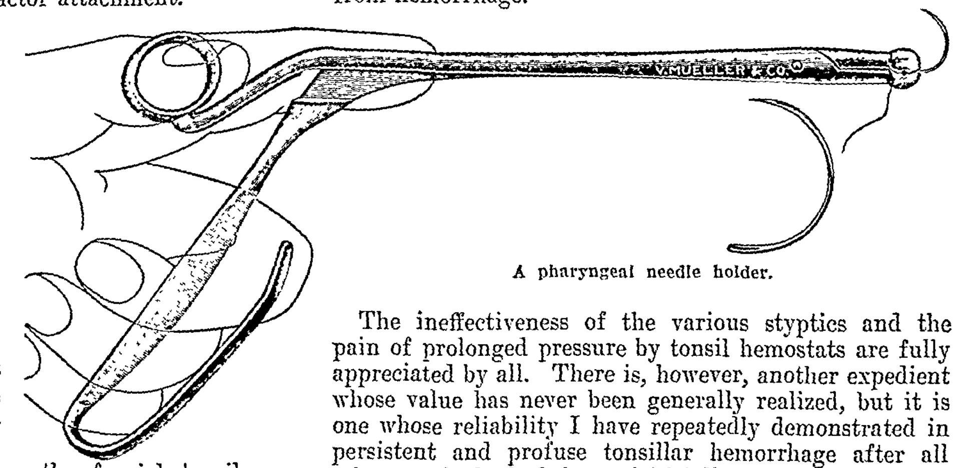
I believe that the primary shock was caused by the pain of the burn and that the condition following was due to the toxic action of the phenol absorbed through the skin.

A NEW PHARYNGEAL NEEDLE HOLDER

DESIGNED ESPECIALLY FOR SUTURING THE TONSILLAR WOUND AFTER TONSILLECTOMY

JOHN O. McREYNOLDS, M.S., M.D., LL.D.
DALLAS, TEXAS

With the substitution of complete tonsillectomy for the simpler but inadequate tonsillotomies of former years there must necessarily develop an increasing danger from postoperative hemorrhage. That the extirpation of the tonsil involves greater responsibility is generally recognized, and we are now concerned with the adoption of such methods as will minimize the risk from hemorrhage.



A pharyngeal needle holder.

The ineffectiveness of the various styptics and the pain of prolonged pressure by tonsil hemostats are fully appreciated by all. There is, however, another expedient whose value has never been generally realized, but it is one whose reliability I have repeatedly demonstrated in persistent and profuse tonsillar hemorrhage after all other methods had been faithfully employed without avail. This consists simply in suturing firmly the tonsillar wound to a sufficient extent to close up all denuded bleeding areas. This may require from one to three sutures, according to the nature of the case, and the stitches may include simply the two pillars of the fauces or they may include within their grasp the tissues at the base of the tonsillar excavation. The suture material which I have found best is a large size of black braided silk. The needles which have proved most satisfactory have been of the Hagedorn variety and of the size and curvature shown in the illustration.

But the factor of by far the greatest importance in the prompt and easy introduction of the sutures is the needle holder. After trying all of the usual forms of needle holders I was led to devise the one here illustrated.

The handle must be so placed that the hand of the operator is always out of the field of vision. The instrument should be able to hold the needle firmly without the use of a lock because it is essential to release the needle quickly after it has penetrated the tissues so that with the same instrument the point of the needle may be grasped immediately and pulled through before the gagging of the patient can dislodge the needle. The grasping surfaces of the instrument should be provided with notches or grooves so that the Hagedorn needles with large eyes can be easily maintained in any desired position. The grasping surfaces at the distal end should present a concavity so that a curved needle may be securely held without incurring the risk of being broken, which would at least be an embarrassing accident in the midst of an operation on a throat filled with blood.

Therapeutics

CONSTIPATION

This condition is so frequently present in American people, and is so generally neglected or treated simply with laxatives and purgatives, often to the future detriment of the patient that, though often considered, we cannot too frequently discuss its proper management. Dietetic mistakes are so often the cause of constipation that a better understanding of the action of different foods on the alimentary canal is necessary properly to treat or manage constipation. As constipation is not always due to imperfect peristalsis, but often is due to impaired intestinal secretion, and as the various kinds of foods stimulate more or less the intestinal secretions, Lafayette B. Mendel, of New Haven, professor of physiologic chemistry at Yale, in a paper read at the last meeting of the American Therapeutic Society (*American Journal of the Medical Sciences,* October, 1909), well says that "the skilled therapist of to-day can well afford to devote to the specific action of the diet the same detailed consideration which he accords to his armamentarium of drugs."

In the stomach, acid is but a slight stimulant to its secretions, but, in the duodenum, acid stimulates, probably reflexly, secretion from the pancreas. By the proper performance of the duodenal digestion a substance is produced called secretin, which stimulates the glands of the intestines to activity. The best promoters of gastric secretion are "dextrins, maltose, dextrose, proteoses, and extract of meat." Mendel says that these stimulants are active at the pyloric end of the stomach, and a hormone, gastrin, is liberated which stimulates the whole secretory function of the stomach.

Nervous influences on gastrointestinal secretion are, of course, well understood. Perfect digestion cannot take place if the patient is suffering great worry or enduring mental frets, or when there is an unpleasant environment, or if non-appetizing food is presented to a patient suffering from intestinal indigestion and constipation. Therefore, a handicap of such surrounding conditions, or associated conditions, must be recognized, and they must be removed if possible.

The mental condition being improved and the food being well prepared and tastefully presented, Mendel's practical dietary facts should be remembered, as the better the digestion the less the constipation. He says that bouillon or meat soup taken early in the meal reaches the pylorus and duodenum and incites a flow of gastric juice. The dextrins and maltose of toasted bread and zwieback act similarly. The increased stomach secretion thus brought about acts as a stimulant to the pancreas and the liver, and plenty of pancreatic juice and bile is the result. Fats and especially oils inhibit the gastric secretion, and this dietary knowledge should be utilized when it has been decided that there is a hyperacidity or an abnormal amount of hydrochloric acid in the stomach; but when there is insufficient gastric secretion, fats and oils should be forbidden.

Varying amounts of acidity in the gastric contents either promote or inhibit the proper opening of the pylorus and the proper discharge of the stomach contents into the duodenum. Mendel says that foods which tend (like proteins) to combine with acid and diminish the free hydrochloric, or (like fats) to repress acid secretion, will delay the discharge from the stomach. When normal acid contents accumulate at the pylorus and are normally discharged into the duodenum, the reflex causes sufficient outpouring of bile to neutralize or render the contents of the duodenum alkaline, and besides this normal aid to intestinal digestion the bile is a stimulant to peristalsis, and intestinal activity is improved. An insufficient acidity of the stomach tends to promote fermentation and may allow intestinal putrefaction to occur. It is also possible, under lessened acid secretion of the stomach, that food may be regurgitated from the duodenum into the stomach. Hence the stomach secretion, especially the hydrochloric acid, being subnormal, fats and oils should certainly be prohibited as tending to make the condition worse.

While it is recognized that intestinal flora may be changed by the administration of certain drugs and possibly by lactic-acid ferments, it is well recognized that radical changes in diet will also change these intestinal conditions, and not only adults but especially infants may have such maldigestions, without objective symptoms, such as diarrhea, as to cause chemical mistakes sufficient to rob the body of necessary elements for its growth. Mendel says an improper amount of fat in the intestines in infants, or fat that is improperly absorbed, may allow the fatty acids to form soaps of calcium and thus rob the child of its necessary lime, which then passes off in the stools. The normal amount of lime, then, not being absorbed into the blood may allow an acidosis, with all its serious symptoms.

This indicates that in all cases of malnutrition, before medication is relied on, the kind of food taken and the character of the digestion, and a more or less thorough analysis of the stools should be made.

Other practical suggestions on the action of food in the stomach are offered by Carl A. Hedblom and Walter B. Cannon, professor of physiology in Harvard Medical School, Boston (*American Journal of Medical Sciences,* October, 1909). These investigators have determined that if carbohydrate food is thinned by adding ordinary amounts of water the rate of the exit of the food from the stomach is not changed, while adding an ordinary amount of water to protein food in the stomach makes the discharge into the intestines more rapid. Hard particles of food retard the evacuation of the stomach into the intestines, while coarse, branny foods leave the stomach quicker than similar foods of finer texture. An abnormal amount of gas in the stomach always delays the passage of food into the duodenum. Whether food is taken hot or cold does not seem to make any material difference in the rapidity with which the stomach contents are discharged into the duodenum, but food with normal acidity in the stomach is passed on much quicker than when the contents of the stomach are hyperacid.

These investigators have also shown that irritation of the colon with croton oil notably retards gastric discharge and delays the movements of food through the small intestine. This experimental fact should be constantly clinically recognized, viz.: that any reflex irritation, from chronic appendicitis, chronic abdominal pain, neuralgic or inflammatory, will inhibit the gastrointestinal digestion, and until the cause of such irritation is removed the digestion will be imperfect and constipation persistent.

Dr. L. M. Gompertz, of New Haven, presented a paper to the American Therapeutic Society at its last annual meeting (*American Journal of Medical Sciences,* October, 1909) in which he discusses the cause of constipation and his treatment without drugs. The length of time from the ingestion of food to the expulsion of the residue of that food from the rectum, Gompertz finds, in thirty individuals, to average from twelve to fifteen hours. In other words, the habit of normal man to have a movement of the bowels in the morning seems physiologically correct to expel the residue of the food of the day before. Certainly, any delay beyond this twenty-four hours would seem non-physiologic and to be a condition that must be actively treated.

Gompertz recognizes two forms of constipation, the atonic and the spastic. The fragmentary, or expulsion of small pieces of feces, he believes to be a part of the spastic form of constipation. The atonic type of constipation he believes is due to an atony of the muscles of the large intestine, and this is usually induced by the over-use of purgatives. He also recognizes that the primary cause of constipation may be an over-absorption of the fluid portions of the contents of the intestines, which would deprive the intestines of residue of sufficient bulk for the musculature to actively contract on it. In the atonic form of constipation the stool is hard and dry, and its caliber may be very large. There is no pain or much increased flatulence, although after such a condition has been in evidence for years, and especially when strong cathartics have been taken, a catarrhal condition of the intestines may develop, there may be fecal impactions, and scybalous deposits may cause local inflammations.

The other cause of constipation is due to a hypertonicity of the musculature of the intestines, which causes spastic constipation. In this form there is usually flatulence and a catarrhal condition of the intestine; spasm of the transverse colon occurs, causing retention of firm masses of feces with resulting fermentation. Colic and pain become frequent symptoms, and in severe cases large amounts of mucus may be passed. In spastic constipation the rectum usually remains empty, except during actual defecation, while in the atonic variety the rectum is more or less persistently filled. In this spastic form of constipation the size of the movements is very small, and they may be even ribbon-shaped.

The systemic disorders that may occur from a constipated habit may be acute, but are likely to be insidious; in fact, it is astonishing how harmless constipation apparently seems to be to some individuals. On the other hand, it is a demonstrated fact that chronic liver inflammation, chronic kidney inflammation, perhaps arterial disease, and certainly mental sluggishness, are conditions that can be, and are, caused by constipation and its consequences. The mental apathy, muscular debility, general malaise, and bad feelings which are so often attributed to malaria or biliousness are frequently entirely due to absorption of toxins from the intestines caused by constipation.

Imperfect stomach digestion due to dietetic errors is perhaps the most frequent cause of constipation, and here a correction of the food is of vital importance and vastly better treatment than the resort to purgatives or even laxatives. Hyperacidity of the stomach Gompertz finds a frequent cause of constipation, and high nervous tension and the eating of too large amounts of meat are probably frequent causes of this hyperacidity. The necessity for physical exercise in those who lead too sedentary a life is, of course, recognized, but such exercise is not frequently enough ordered.

It is probably frequent that not sufficient water is taken by the patient, and, on the other hand, that the fluid contents of the intestines are too rapidly absorbed. In either case, the advantage of weight and gravity is lost and the advantage of bulk for the intestines to act on is lost, the dryness and stickiness of the fecal matters is increased and the ability to expel them is diminished. To overcome such a condition Professor Lafayette B. Mendel advises the ingestion of a substance that will hold water in its meshes, and such a substance is agar-agar. The theory suggests, and the fact demonstrates, that when agar-agar is ingested and becomes mixed with fecal matters in the lower intestine, that it, retaining water, makes the fecal masses more bulky, more watery, more pultaceous, and hence of a consistency that is easily propelled and expelled. Agar-agar also fortunately resists bacterial decomposition.

Gompertz experimented with agar-agar as an addition to the diet of thirty patients who were suffering from constipation, the age of these patients varying from 15 to 83 years, and the majority of them being unable to have a movement of the bowels without the aid of drugs. The agar-agar was taken in the morning and evening, beginning with 15-gram (half-ounce) doses, and in most instances was eaten with milk or cream, the same as a breakfast food. In all but two of these thirty patients regular movements of the bowels began after the agar-agar had been taken from one to three days. After regular movements of the bowels had been established, the agar-agar was in most instances gradually reduced in amount. The duration of the treatment was from one to three months.

The agar-agar should be prepared in granular form, i. e., ground up fine, and can be eaten as a powder with cream or milk, as suggested, with the addition of sugar or salt to suit the taste. Such agar-agar was prepared by a local druggist.

Certainly any recommendation, either from a regulation of the diet or a change in the habits of the patient, or the addition of some simple article to the diet as suggested, that cures constipation, should be looked on as a distinct advance in treatment of this obstinate condition.

As another dietary suggestion in the treatment of constipation, Dr. Anthony Bassler, of New York (*Dietetic and Hygienic Gazette,* September, 1908), recommends the following laxative food for children who are afflicted with constipation:

BRAN GEMS

2 cups of bran.
2 cups flour.
1 cup milk.
¼ cup molasses.
½ teaspoonful baking soda (dissolved in hot water).
½ teaspoonful butter.
½ teaspoonful lard.
Salted to the taste.
Bake in a slow oven for forty-five minutes.

Bassler suggests that little children eat several of these gems after coming home from school in the afternoon, as he finds that they have a pleasant laxative effect.

A method of treating constipation other than by drugs has lately received considerable approval, viz., oil injections into the rectum. A soft rubber catheter may be inserted three or four inches up into the sigmoid flexure, the patient lying on his left side, and then from 100 to 150 c.c. (3 to 5 ounces) of warm sweet oil is injected by means of a fountain syringe. This oil should be retained, if possible, over night, and if the movement of the bowels in the morning is not satisfactory a small saline enema may be administered. This oil injection should be repeated daily for a week, then every other day for two weeks, and then once or twice a week for some period of time. The treatment in instances of dry feces and sluggish activity of the rectum is many times successful, and this treatment is again far in advance of the continued administration of cathartics and laxatives.

THE PATHOLOGIC ANATOMY OF CHRONIC ALCOHOLISM

In stating the causes of almost all the chronic, non-infectious diseases, it is a time-honored custom of the texts to include alcohol; and generally it is given a prominent place along with syphilis, followed at a respectful distance by gout and lead. Consequently the student comes to consider that not only is cirrhosis of the liver a usual result of alcoholism, but that nephritis, myocarditis, arteriosclerosis, and sundry disorders of the central nervous system also are commonly caused by it. The pathologist whose experience lies with the outcasts of great cities, however, knows well that the most alcoholic of his subjects are often free from nearly all, if not all, of these indurative processes, just as he observes that old prostitutes may show no evidences of inflammatory disturbances in the pelvis. On account of the common misconception of the anatomic changes produced by chronic alcoholism, it is worth while to consider just what conditions are and what are not found in the bodies of habitual drunkards.

In the city of Hamburg, as in other large and active seaports, there die annually many wanderers and outcasts brought low by drunkenness. At the last meeting of the German Pathologic Society there was reported by Fahr a series of three hundred and nine autopsies performed at the *Hafenkrankenhaus* (harbor hospital) of Hamburg on victims of chronic alcoholism, dying from either alcoholism alone or from other causes, no less than ninety-eight being suicides. In nearly all the cases the alcohol had been taken in the form of spirits, not as beer or wine. The results of these autopsies are distinctly not in harmony with the conception that alcohol is a poison which produces wide-spread and gross anatomic changes throughout the body, or that it is a common cause of either arteriosclerosis or nephritis. Even cirrhosis of the liver is far less common in alcoholics than it is usually supposed to be, for, of the three hundred and nine cases, in but eleven was cirrhosis the cause of death; in two other bodies there was an advanced cirrhosis, but death was due to some other cause. Of one hundred cases of cirrhosis in which autopsies were performed by Simmonds in Hamburg, alcoholism could be excluded in fourteen; in sixty it was evident, and in twenty-six there was no reliable information as to alcohol; therefore it must be concluded that, while only a very small proportion of drunkards suffer from cirrhosis (about 4 per cent.), there are not a few cases of advanced cirrhosis which are not due to alcoholism, although alcohol is responsible for far more than a majority of all cases of cirrhosis. On the other hand, in nearly every case of habitual drunkenness the liver shows fatty changes, usually severe, but not ordinarily associated with connective tissue increase; and this is by far the most frequent change in alcoholism. Next to the fatty liver in frequency, and probably much more important in its effects, comes chronic leptomeningitis, which was present in about half the cases. Fatty infiltration of the heart wall was present in 30 per cent., and chronic gastritis in 20 per cent. On the other hand, chronic nephritis caused the death of but eight of the three hundred and nine drunkards, and nephritis was found much less frequently among the alcoholic subjects in the harbor hospital of Hamburg than in the hospitals which receive patients of better habits. So, too, arteriosclerotic changes were certainly no more, and apparently somewhat less common and extensive among the bodies of alcoholics than among those of non-alcoholics of corresponding age. It would, therefore, seem unjustifiable to consider that alcohol, even when used in great excess, is of itself a common cause of either nephritis or arteriosclerosis.

It is a striking fact, and one familiar to pathologists, that a large proportion of deaths in chronic alcoholism occur without any anatomic alteration being found which is adequate to account for the death; this was the case in seventy-one of the three hundred and nine autopsies studied by Fahr. In such cases the fatty liver is almost invariably present, frequently chronic leptomeningitis, chronic gastritis, and fatty infiltration of the heart; but nothing to explain the sudden deaths, unless some are caused by failure of the fatty heart. Fahr suspects that changes in the ganglion cells of the heart may be responsible for the sudden heart failure, but as yet no anatomic proof has been forthcoming to support this hypothesis. It is interesting to note that protracted feeding of alcohol to guinea-pigs and rabbits failed to cause the fatty liver and other anatomic changes that are common in man, but the animals showed the same tendency to die suddenly and unexpectedly.

GOVERNMENT COOPERATION FOR IMPROVING THE PHARMACOPEIA

Few, if any, public health measures are of more direct importance than efficient regulation of the purity and identity of widely recognized medicaments and reasonable regulation of their use or, at least, restriction of their abuse. To secure a fuller appreciation of the uses and limitations of drugs is to benefit the public at large as well as to advance the development of the science of medicine.

It is gratifying, therefore, that the United States Public Health and Marine-Hospital Service has recognized the importance of drugs and drug standards in public health work and is now cooperating in a practical way with the Committee on Revision of the Pharmacopeia to improve our standards for drugs and to promulgate a knowledge of the true values or shortcomings of official medicaments. Our readers will, no doubt, be interested in the series of bulletins constituting a "Digest of Comments on the Pharmacopeia of the United States of America," which, by request of the Board of Trustees of the United States Pharmacopeial Convention, is now being compiled and published under the direction of the Surgeon-General of the United States Public Health and Marine-Hospital Service. The first of these bulletins[1] contains considerable material bearing directly on the shortcomings and needs of the Pharmacopeia. It indicates very well the degree of faithfulness with which the present Committee on Revision of the United States Pharmacopeia has adhered to the general principles or instructions of the Pharmacopeial Convention. It also shows the compliance, or rather lack of compliance, with the protocol of the Brussels Conference for the unification of formulas for potent medicaments, and thus further emphasizes the need that medical practitioners should interest themselves in a practical way in the making of the Pharmacopeia which they are to follow, if for no other reason than to keep fully abreast of the advances in medical science abroad.

Apart from the criticisms on the scope and the contents of the United States Pharmacopeia, and in addition to the material of a purely chemical or pharmaceutical nature, this bulletin contains much that will interest physicians generally. Thus, the references to the present-day use of the several drugs will be found a fair indication of the usefulness of certain medicaments, while the references from homeopathic and eclectic medical journals indicate some of the fallacies of sectarianism in medicine. They also appear to bear out the oft-repeated assertion that in the application of really useful medicaments there is no essential difference between the graduates of the several schools.

The present work is essentially a continuation of the "Digest of Criticisms" on previous revisions of the United States Pharmacopeia formerly published by the Committee on Revision through its Chairman, the late Dr. Charles Rice, and largely compiled by the late Hans M. Wilder. This was of inestimable value in connection with former revisions of the Pharmacopeia. The present series of "Digest of Comments" will, no doubt, be equally useful to the Committee on Revision to be elected at the forthcoming Pharmacopeial Revision Convention. Physicians generally, and delegates to the Pharmacopeial Revision Convention particularly, who wish to familiarize themselves with the needs of the Pharmacopeia of the United States will find much in this bulletin that will interest them and suggest profitable lines of activity.

THE PERSONAL EQUATION IN MEDICINE

The theory of medicine, as of all other sciences, has often been affected by the personal equation—that constant error to which each individual is subject to a greater or less degree. Each observer, though he may be able to see facts clearly and even to trace the relation of cause and effect among them to some extent, is liable to error in the interpretation of those facts in proportion to the degree of his fixed personal bias, whether that personal bias be in favor of a widespread belief or merely of a little private theory of his own.

That acute observer of human nature, Rudyard Kipling, in a recent story,[1] creates a significant and not essentially improbable illustration of the workings of the personal equation in medical theory.

A practitioner of medicine who is likewise a devout believer in astrology (so runs Kipling's tale), in the days of the Great Rebellion in England, comes into a little village which is being devastated by the plague. He exhausts all the resources of the medical art of his time in vain; the people continue to despair and die. The physician, therefore, resolves to take counsel of the stars, through which he learns that the patroness of the pestilence is our Lady of Ill Aspect, the moon; and that the only hope for the dying people lies in the aid of the sun and the planet Mars. By chance the astrologer-physician sees some rats staggering and dying in the moonlight; and the idea of a connection between the rats and the plague flashes across his mind—not, indeed, that he for a moment entertains the idea that the rats carry contagion, but that, being creatures of the night and, therefore, of the moon, the rats must be parties to the sidereal conspiracy of which the plague is the outcome. So the doctor brings his patients away from the dark holes and hovels where they have been languishing, and takes them into the sunshine and fresh air—not because fresh air and sunshine are good in themselves, but because the influence of the sun, being opposed to that of the moon, is the proper one to seek. He organizes a war of destruction against the rats; and in the process of extermination all the dark, filthy places in the village are made light and clean—not, of course, because such a procedure is hygienic, but because it invites the favor of the sun and lessens the unfavorable influence of the moon. He causes the holes of the rats to be filled with slag from the village smithy—because the horse is a martial animal, and Mars is a favorable planet. The people are aroused from their apathy and terrified inertia by the tasks set them and the renewed hope held out to them; the village is cleansed and made hygienic; the rats are destroyed and the plague vanquished. The physician, regarded with adoration by the grateful people of the village, with becoming humility ascribes all merit to the favorable stars.

---

[1] A Doctor of Medicine, Delineator, October, 1909.

Now, we may smile at the fanciful idea that the modern expedients of killing rats and rendering dwellings sanitary to rid a community of plague, if successfully practiced in the seventeenth century, might have strengthened the belief of physicians and laymen in astrology. There is food for a few moments' sober reflection, however, in this imaginative glimpse into the past.

Prejudice and prepossession did not die with the belief in astrology, nor are they the exclusive possessions of the ignorant in our own time. Science may warn against the error involved in the personal equation, but cannot destroy it, even where scientists are concerned. The danger is ever to be guarded against that some unsuspected factor—some idea which has taken possession of the mind unquestioned and whose sway has been taken for granted, like the belief in astrology in the mind of Kipling's physician—may prevent us from attaining some truth that waits near at hand to be discovered, like the age-long relation between infectious diseases and the filth in which they are bred and the noxious creatures by which they are conveyed.

WORTHLESS DRUGS

An important part of the work of the Council on Pharmacy and Chemistry is the investigation of non-proprietary drugs with the object of determining whether they are of sufficient value to be included in New and Nonofficial Remedies. These non-proprietary remedies are of two kinds: those recently introduced and those which, while in no sense new, are not to be found in the Pharmacopeia because they were considered as of little or no value. Drugs of the latter class are periodically resurrected and, by enthusiastic reports, made to all intents and purposes, "new" remedies. As Sollmann has said,[1] "The physician who is impressed by these reports naturally desires some unbiased and reliable information about them, as well as about the remedies which are actually new. The ordinary reference books, however, give but very scanty data; they necessarily lack the elasticity which is essential for the proper presentation of a new subject. Above all, a physician who desires to try these new remedies should be assured that they are of a uniform quality; but with them there are no established standards of any kind."

In the case of proprietary articles the Council has not required, as a condition of admissibility to New and Nonofficial Remedies, that their therapeutic value shall be demonstrated, but only that no grossly exaggerated therapeutic claim be made for them. Non-proprietary substances, on the other hand, have been admitted only when they appeared to possess positive medicinal value. This policy has resulted in the rejection of a considerable number of drugs, mainly from indigenous American plants, which have been used to some extent, but for which no definite therapeutic value has been shown. Since many of these drugs are made the essential ingredient of proprietary mixtures for which grossly extravagant claims are made, the Council has prepared several short articles to show on what basis the claims for the value of these non-proprietary drugs rest. In most cases it appears that such claims are based on reports of clinical experience and observations by untrained and little-known men. In these articles the Council has frequently found it necessary to refer to reports of little or no scientific value; in fact, these references, together with the lack of any available data from prominent medical authors, indicate the paucity of real evidence in regard to these drugs. Even the so-called clinical evidence is in many cases shown to be, not the honest expression of enthusiastic though incompetent observers, but rather of the nature of "patent medicine" testimonials or paid write-ups.

In the Pharmacology Department, in this issue, appears the first article of this series. It deals with echinacea, a drug which is the chief constituent of a number of nostrums for which ridiculous claims are made, and the article shows in a striking manner on what feeble evidence the asserted virtues of the nostrums containing this drug are based. In subsequent issues reports will appear on other non-proprietary drugs of doubtful value which form the prominent constituents of innumerable nostrums.

THE ATTEMPT TO DEGRADE THE SANITARY SERVICE AT THE ISTHMUS

Any doubt that an attempt is being made to degrade the Sanitary Department at the Isthmus is removed by the letter of Mr. Mann to the Bureau of Legislation, printed in the Department of Correspondence in this issue, and by a study of the bill now pending in Congress, to which that letter relates. The bill in question (H. R. No. 5155; S. 601), now in committee at both ends of the Capitol, was introduced almost simultaneously, in the House, by Mr. Mann, of Illinois, and, in the Senate, by Mr. Crawford, of South Dakota. Its printed title is "A Bill to provide for the government of the Canal Zone, the construction of the Panama Canal and for other purposes"; but it ought to read: "A Bill to provide for the appointment of one director, one chief engineer and one governor and to subordinate the chief sanitary officer to any one or all of these officers." That, at least, is the meaning of the bill when divested of all ambiguity, a meaning that becomes obvious when, in Section 3, Paragraph 3, it is proposed to dispose of the whole situation at the Isthmus by appointing the three officers first mentioned as the heads of coordinate departments, with no more mention of the Sanitary Department than if it did not exist. If this department is not specifically included in the list of designated departments it is excluded; and if it exists and is excluded, it must become subordinate to something that is included. This is a very old legislative ruse and one that is obviously brought into requisition at this time for the same old purpose of putting the country to sleep while a measure to which the people would naturally object is quietly rushed through Congress.

---

[1] Sollmann, Torald: The Broader Aims of the Council on Pharmacy and Chemistry, The Journal A. M. A., July 18, 1908, li, 237.

That the people in general will object to this measure when they realize what it means is a safe assumption. That the medical profession in particular will firmly but insistently oppose it, now that its hidden design has been made apparent, is a certainty. And that the antagonism in both instances will be based on the soundest reasons becomes apparent the moment certain salient facts in the history of the Isthmian project are taken into account. Thus, it will be recalled, when the Government took over the Panama enterprise, now something over six years ago, it was very generally recognized that the French had reduced the feasibility of moving the dirt to a demonstration. But it was recognized with even more unanimity that the one remaining barrier to success was the sanitary control of conditions that had defeated every former attempt by converting the Isthmus into a veritable Golgotha.

In this emergency every eye turned as by a common impulse to Colonel William C. Gorgas, Medical Corps, U. S. Army, who, by virtue of his sanitary triumph over Havana, stood as the one man for this herculean task. It was known, however, that he had been able to succeed in Cuba only because he had been given an absolutely free hand by his military commandant, General Leonard Wood, who, being a medical man as well as a soldier, had the special intelligence necessary to comprehend the situation. And it was furthermore recognized that Colonel Gorgas must have a similarly free hand in order to be equally successful in Panama. Physicians in every part of the country accordingly petitioned President Roosevelt to make him an actual member of the commission on a footing of equality with the other members. This request, however, was not complied with, and Colonel Gorgas, who was to solve the problem on which the success of the whole enterprise depended, was designated as "Chief Sanitary Officer," with a status "subordinated in the seventh degree below the actual head of executive authority."

The result of this action was brought to the attention of the country by the report on Isthmian Canal Sanitation by Dr. Charles A. L. Reed.[1] It was there shown that the Sanitary Department, in consequence of that action, was hampered in everything that it undertook; that it was subjected to the most annoying infringements on what from the start ought to have been recognized as its exclusive prerogatives; that red tape impaired its efficiency; that presumptious interference by ill-informed superiors hampered its progress; and that its moral and educational force on the Isthmus was lessened by its position as an underlying service. The furor excited by this revelation was followed by the reorganization of the commission. Colonel Gorgas was made a member of that body as he ought to have been at the start. He was given authority to report direct to the chairman of the commission, just as other heads of departments were authorized to report. This somewhat tardy change made the Sanitary Department a coordinate instead of a subordinate branch of the Isthmian organization, and that is the satisfactory status which it occupies to-day.

While occupying this position and largely as a result of the freedom of action thus vouchsafed to it, the Sanitary Department of the Isthmian Canal Zone has achieved results that to-day not only command the applause of the civilized world, but that have resulted in the selection of Colonel Gorgas, the chief of that service, as the official head of the organized medical profession of America. Yellow fever, the perennial dread of the tropics, has been banished; malaria, the real pest of the Isthmus, has been reduced to a minimum; the bubonic plague had been challenged at the portals and denied a foothold; devastating endemics have been made things of the past; disease-breeding centers have been abolished; the cities of Panama and Colon—the control of which by the Sanitary Department, stipulated by treaty, is another reason why it should not be subordinated to any other department—these cities, once pestilential, have been made salubrious; while as a natural result of the fact that disease and death are no more common there than in many cities in the states, a sense of security has been imparted to the more than forty thousand persons to-day employed in the zone, and the success of the enterprise has thus been assured. And all of this has been and is being done in a land previously so dangerous to human life that it had become a byword and a reproach among the nations of the world. In the face of this matchless record, the proposition to degrade the service by which these results have been achieved—to place it back in the position of underling in which it was first placed—will come as a shock to the people.

The statement now made by Congressman Mann that "it is not possible to have good government on the zone with a lot of different heads" is, of course, thoroughly disingenuous. If there is to be only one head, then why does his bill designate three heads? And if three heads, why not four? And if not four heads, why not subordinate some department besides the one on which, without disparagement to others, is the very one on which the success of the whole enterprise depends? Then, too, has there not been good government in the zone with sanitation in the hands of a coordinate rather than a subordinate department? In short, has anything on the Isthmus come as near "making good" as the Sanitary Department? The people have so far voted hundreds of millions of dollars for the canal and they stand ready to vote as many more as may be necessary to complete it. But they insist and will insist not only that the money shall be judiciously expended, but that the whole enterprise shall be so safeguarded that, by the humane protection of life and health, there will be some prospect of its ultimate completion.

---

[1] THE JOURNAL A. M. A., March 11, 1905.

It may be asserted, without fear of successful contradiction, that nothing has so contributed to public confidence in the ultimate success of the canal as the achievements of its Sanitary Department. The American people now demand that that department be left with freedom of action, that its efficiency be promoted rather than hampered, and, finally, that Congress treat it with the consideration befitting its demonstrated efficiency, its well-earned honor and its justified dignity.

MANSLAUGHTER AND HYPNOTISM

In some countries there are laws prohibiting public exhibitions of hypnotism. There should be such here. The traveling exhibitors who make their living by making fools of their fellow beings are not useful members of society. There is, in the first place, a peril in submitting oneself to another's will; and that is what the subject generally understands he is doing, though it is not by any means necessarily the fact. Another more immediate danger is shown by the recent occurrence in New Jersey—a possible direct danger to the life of the subjects. Especially is this true of such demonstrations as are reported to have been made in the case referred to, in which the operator stood on the rigid body of his subject, supported only by the head and feet. Such a performance is not suitable for a public exhibition, and we cannot think of any good reason why it should be for a private one. It may be true that it is often done without harm, but the autopsy findings in this case, as given through the press, strongly suggest that it was the cause of death. Public exhibitors of hypnotism may take the trouble to ascertain the physical fitness of their subjects, but we believe that this is rarely done, and many ugly possibilities show up on consideration of the subject. Leaving out of account the common belief which has sometimes manifested itself in our courts, that hypnotism may be responsible for involuntary crime, it is an abnormal condition and should not be too freely induced—certainly not without good reason.

Medical News

ILLINOIS

Personal.—Dr. Everett H. Butterfield, formerly director of the Ottawa Tent Colony, has been made medical director of the Buffalo Rock Sanatorium for the Treatment of Tuberculosis, Ottawa.——Dr. Henry E. Wagner, Chicago, has returned from Europe.——Dr. Adolphus P. Standard, assistant surgeon at St. Francis Hospital, Macomb, has resigned and will take charge of the new Graham Hospital at Canton.

State Supplies Free Antitoxin.—The State Board of Health announces that the refined and concentrated diphtheria antitoxin, which it supplies free of charge to all who need it in Chicago, is furnished by manufacturers operating under government license; that the antitoxin is of the highest quality and degree of purity, and in the opinion of the board, of higher potency than any serum in the market. In a recently-awarded contract, the unit of strength of antitoxin was as follows: 1,000 unit packages, 1,200 units per c.c.; 2,000 unit packages, 1,600 units per c.c.; 3,000 unit packages, 2,000 units per c.c.; and 5,000 unit packages, 2,500 units per c.c. The board expresses its belief that the appropriation of $8,000 per annum made for the free distribution of antitoxin in Chicago, will be sufficient to supply the needs of that city.

Chicago

To Aid Tuberculous Children.—The United Charities of Chicago, by the aid of a grant of $2,500 made November 15, from the Elizabeth McCormick Memorial Fund, will inaugurate an open-air school to be conducted in tents on the roof of the Mary Crane Nursery on Ewing street. At the outset, twenty-five children will be treated in the school.

Extensive Sanatorium Proposed.—At a meeting held in the Chicago Athletic Club, November 18, a plan was launched for the establishment of a large sanatorium near Las Vegas, N. M. It is proposed to purchase between 100,000 and 200,000 acres of land, comprising the old Valmore Ranch. When fully improved the institution will accommodate more than 1,000 patients. The sanatorium is to be exclusively for sufferers from tuberculosis who are not poor enough to accept state aid, but are unable to provide for the travel and care they need. An effort will be made to limit admissions to those patients, who in the best judgment of the examiners, give promise of a cure.

The Cost of Tuberculosis in Chicago.—The Department of Health, in the current issue of its *Bulletin*, gives the approximate cost of tuberculosis to the people of Chicago during 1908 as $23,635,190, distributed as follows: The money value of lives lost amounted to $19,571,950; the wages lost by the decedents amounted to $1,336,200; the cost of the illness of those who died, $707,040; the loss of wages of patients still living, $1,120,000, and the cost of illness of 10,000 living patients, $900,000. During the first nine months of the current year, 3,024 new cases of tuberculosis were reported to the department of health, equivalent to 136 per 100,000 of population. These new cases were distributed as follows: Business and factory wards, 482 per 100,000; poor residence wards, 188; fair residence wards, 158; good residence wards, 104; and semi-suburban wards, 87 per 100,000. This demonstrates that the cost of tuberculosis falls most heavily on the poorer people in the city.

KENTUCKY

Changes in Louisville Health Force.—The mayor has appointed Dr. William Ed. Grant health officer; Drs. Ezra O. Witherspoon and Griffin C. Kelly, assistant health officers; Dr. J. W. Fowler, superintendent of the City Hospital; Dr. Jesse I. Whittenberg, superintendent of the Eruptive Hospital; Drs. Heman Humphrey and Charles J. Rosenham, city physicians, and Dr. Fred L. Wilhoit, sanitary inspector.

Against Tuberculosis.—Articles of incorporation of the Kentucky Association for the Study and Prevention of Tuberculosis were filed with the clerk of Jefferson county, October 27. The object, as stated, is to encourage local associations for the study and prevention of tuberculosis. On the first board of directors are the names of Drs. Henry S. Keller, Louisville; R. W. Thompson, George P. Sprague, Lexington; Dunning S. Wilson, Louisville, and Jacob Glahn, Owensboro.——The Lexington Antituberculosis Association, at its annual meeting, November 14, elected the following officers: Dr. George P. Sprague, president; Dr. Nathan R. Simmons and R. C. Ware, vice-presidents; Thomas Johnson, treasurer; Mrs. Claude Garth, secretary, and Mrs. Judge Lafferty, Dr. Thomas C. Holloway and Dr. Orrin L. Smith, executive committee.

MARYLAND

County Society Meeting.—At the annual meeting of the Washington County Medical Society, held at Hagerstown, November 11, the following officers were elected: President, Dr. DeWitt C. R. Miller, Mason and Dixon, Pa.; vice-president, Dr. William A. Quinn, Chewsville; secretary, Dr. Samuel M. Wagaman, Hagerstown; treasurer, Dr. Hamilton K. Derr, Hagerstown, and censor, Dr. V. Milton Reichard, Fairplay.

Personal.—Dr. Charles A. Wells, recently elected state senator from Prince George county, was tendered a reception by his friends at Hyattsville, November 13.——Dr. James H. Jarrett, Towson, has recovered from his recent illness.——Dr. Harry V. Harbaugh, East New Market, suffered severe burns on the face October 14, by the explosion of an automobile lamp.——Dr. William H. Fisher, of the staff of the Springfield State Hospital for the Insane, has resigned, and Dr. E. P. Harrison has been appointed assistant physician.——Dr. Joseph W. Reynolds, Cecil county, is reported to be seriously ill with disease of the stomach.

Health Recommendations.—The Commission of Hygiene and General Health has recommended to the governor an increase in the appropriation for the State Board of Health to allow for the extension of its work. He recommends that the work of the board be divided into five bureaus; that provision be made for the proper supervision of the water supply and sewerage; the creating of the office of sanitary engineer; the employment of sufficient draftsmen and inspectors, and the appropriation of $1,000 a year for the publication of a popular health bulletin.

Baltimore

Personal.—Dr. Frederick Taylor returned from Europe November 15.——Dr. Harry L. Homer has been made assistant physician of the Union Protestant Infirmary.——Dr. Ira Remsen, president of Johns Hopkins University, has been elected trustee of the Carnegie Foundation, vice President Eliot of Harvard University, retired.

MASSACHUSETTS

Needs of Infirmary.—At a meeting of the directors of the New Bedford Antituberculosis Association, held November 1, it was reported that there were twenty-four patients in the sanatorium of the association, and that three vacancies existed. Up to the present time, the amount pledged for the new sanatorium amounts to $20,500, and $7,000 is still needed before the buildings can be completed.

Woman's Hospital Opened.—The Free Hospital for Women, Brookline, was opened for inspection November 4. The institution has recently been much enlarged and improved. It is devoted to the treatment of diseases peculiar to women and is an entirely free institution. It has a present capacity *of fifty-four beds which are occupied only by surgical* patients. The medical staff is under the direction of Dr. W. P. Graves.

Infectious Diseases.—During September there were reported to the State Board of Health 466 cases of diphtheria, 105 of measles, 382 of scarlet fever, 491 of typhoid fever, 585 of tuberculosis, 13 of cerebrospinal meningitis, 47 of whooping cough, 46 of varicella, 9 of ophthalmia neonatorum, 2 of tetanus and 1 each of erysipelas, mumps, smallpox and trichinosis.

Endows Bed.—By the will of the late James Ingram, Lawrence, $5,000 is devised for the maintenance of a bed in the Lawrence General Hospital, to be named after the testator.

MISSOURI

Personal.—Drs. Byron N. Stevens, Chillicothe, and John L. Burke, Laclede, have been appointed pension examining surgeons.——Dr. Malcolm M. Campbell, Albany, was thrown from his buggy in a runaway accident recently, fracturing two ribs.——Dr. Frank B. Fuson, Springfield, has been appointed a member of the State Board of Health, vice Dr. Frank J. Lutz, St. Louis, term expired.

Licenses Revoked.—The license of Dr. Charles W. Hume, Columbia, was revoked for fifteen years by the State Board of Health, at its meeting in Jefferson City, October 21, on the charge that he had written prescriptions for liquor. No defense was made.——Dr. Joseph T. Bazan, Glasgow, is said to have had his license revoked by the State Board of Health.

School Inspectors.—The Health Commission of Kansas City has selected the following inspectors of public school pupils and buildings: Drs. Hasbrouck DeLamater, Scott P. Child, Archie N. Johnson, Jesse E. Hunt, E. F. DeVilbis, Eugene P. Hamilton, William J. Thompkins and Otho L. McKillip.

Dinner for Dr. McAlester.—The physicians of Columbia and members of the faculty of the University of Missouri are planning a dinner in honor of Dr. Andrew W. McAlester, formerly dean of the school of medicine. At the dinner a book will be presented to Dr. McAlester, containing autographs of his former students.

St. Louis

Personal.—Dr. Kenneth W. Millican has been appointed, by the Municipal Commission on Tuberculosis of St. Louis, editor of its bulletin.——Drs. Arthur H. N. Juengel and Melton, internes in the City Hospital, are ill with diphtheria.

New Hospital Staff.—At the request of the Alexian Brothers' Hospital of St. Louis, the St. Louis University has named the following staff: Dr. Charles H. Neilson, physician and chief of staff; Dr. John W. Marchildon, genitourinary department; Dr. Major G. Seelig, surgeon; Dr. Carroll Smith, assistant surgeon; Dr. William W. Graves, neurologist; Dr. Albrecht Collasowitz, oculist; Dr. Otto L. Von der Au, laryngologist; Dr. Ralph L. Thompson, pathologist, and Dr. George C. Crandall, consulting physician.

NEW HAMPSHIRE

State Sanatorium.—The State Sanatorium for the Care and Treatment of Tuberculosis received its first patients September 14. The following official examiners have been selected up to date: Drs. Samuel R. Upham, Claremont, N. H., John D. Proctor, Keene, and Miah B. Sullivan, Dover. The rate of board is $10 per week. Any applicant who is unable to pay the board rate will be referred to the State Board of Charities and Corrections, which will fix the rate to be paid. When in full running order, the sanatorium will accommodate from thirty-five to forty patients. It is situated on the side of Mount Moosilauke, an elevation a little more than 1,600 feet. The buildings in the institution consist of a two and one-half story administration building containing dining room for patients, physician's office, laboratory, sitting room and quarters for the employees, and two detached ward buildings with wide piazzas, and rooms sufficient to accommodate all the beds. Dr. P. Charles Bartlett, Warren Summit, is the superintendent, and he will examine patients at the office of Dr. Wheat, Manchester, on the first and third Tuesdays of each month, between 11 a. m. and 1:15 p. m.

Personal.—Dr. Noel E. Guillet has been elected president of the Manchester Medical Society, vice Dr. Walter T. Crosby, resigned.

NEW YORK

Want Hospital Pensions.—The conference of medical superintendents and managers of state hospitals, together with the members of the State Lunacy Commission, have decided to favor legislation at the coming session of the legislature to provide for an increase of about 20 per cent. in the salaries of attendants and nurses in the state hospital service. A paper was presented recommending that annuities be paid not only to employees but also to members of the medical staffs of state hospitals if they retire after twenty-five years' service. This proposition was endorsed by the conference and a committee was appointed to confer with the lunacy commission in the drafting of necessary legislation.

Wishes to Maintain Sanatorium.—The Metropolitan Life Insurance Company has caused to be filed with the clerk of Albany county, a writ of certiorari in the matter of its application to the state superintendent of insurance for approval of plans to buy land on which to maintain a tuberculosis sanatorium, and in which the superintendent denied the application. In its papers, the insurance company asserts that the superintendent of insurance has power to pass on the application, holding that it is a proper purpose for a company to conserve its assets by cutting down its death rate.

Health Officers Effect Organization.—At the ninth annual conference of sanitary officers of the state, held in Rochester, November 11 and 12, organization was effected, and the following officers were elected: President, Dr. Robert Simpson, Jr., Volney; vice-presidents, Drs. Robert M. Andrews, Bergen, and David M. Totman, Syracuse; secretary, Dr. Montgomery E. Leary, Rochester; and treasurer, Dr. William Stanton, Webster. One officer from each county will report proposed laws and rules for adoption at the next conference.

Personal.—From the list of examiners of the State Board of Medical Examiners, which appeared in THE JOURNAL, November 13, page 1649, the name of Dr. Ralph H. Williams, examiner in physiology, was accidentally omitted.——Dr. Jason Parker has been made secretary of the board of health commissioners of Jamestown, and Dr. Morris N. Bemus has been appointed a member of the local board of health.

Emma Calvé Camp Opens.—The New York Throat, Nose and Lung Hospital has opened its tuberculosis annex and night camp immediately adjoining the present hospital building. The annex has fifty beds. The camp is named in remembrance of the singer who gave a concert at which a large sum was raised for the hospital. The camp is intended for men only, who go there after their days' work is done.

Medical Library Association Elects.—The Utica Medical Library Association, at its annual meeting, held November 8, elected Dr. Raymond L. Baker, president; Dr. Thomas C. Gifford, vice-president; Dr. Angeline Martine, secretary; Dr. Charles H. Baldwin, *treasurer; and Dr. Smith Baker, librarian.*

Appropriation for Tuberculosis Hospital.—The Board of Supervisors of Monroe county, on November 3, adopted a report calling for an additional appropriation of $75,000 for a site and buildings for a tuberculosis hospital to be established on the county farm in the town of Brighton.

New York City

New Home of the Health Department.—Mayor McClellan has laid the cornerstone of the new office building of the Department of Health, at Willoughby and Fleet streets and Flatbush avenue, Brooklyn. Dr. Thomas Darlington, health commissioner, and Dr. Joshua M. Van Cott, president of the Kings County Medical Society, were the speakers. The cost of the building will be about $350,000, and it is hoped that it will be ready for occupancy by January 1.

Personal.—Dr. Ernest Sachs has been appointed to the new surgical department for diseases of the nervous system just established at the Beth Israel Hospital.——Dr. Charles Hoffman has been elected professor of electrotherapeutics in the New York School of Clinical Medicine and the West Side German Dispensary.——Dr. John M. Wheeler has been appointed assistant surgeon in the ophthalmic department of the New York Eye and Ear Infirmary.

German Hospital Dinner.—The German Hospital Dispensary celebrated its fortieth anniversary by a dinner at which Professor Hallock of Columbia University and Dr. August Zinsser made addresses. Gifts of $5,000 each were announced from Mr. Max Richter and Mrs. Victor Bayer. On this occasion Dr. Zinsser received an honorary degree from the University of Giessen, Germany, and Dr. Otto G. T. Kiliani was presented with the order of the Crown in the third degree by Rudolf Franksen, German Consul General, who was the bearer of a letter from the Chancellor of the German Empire. Drs. Rudolf C. L. Denig and Louis Peiser each received the order of the Red Eagle in the fourth degree.

More Hospital Space Needed.—The annual report of the Charity Organization Society sets forth the most urgent need of more beds and hospitals for the victims of tuberculosis in order to meet the increased overcrowding which are found throughout Manhattan and the Bronx. The situation in Harlem and the Bronx is becoming a problem by itself. They also urge more playgrounds, industrial schools, day nurseries and diet kitchens. More than 70,000 visits were made to families and nearly $85,000 has been disbursed in material relief. The Special Employment Bureau has been endeavoring to solve the problems of occupations for cripples and for cases of arrested tuberculosis.

Harvey Society Lectures.—The fifth course of Harvey Society Lectures began October 30 with a lecture by Dr. Richard M. Pearce on "The Problems of Experimental Nephritis." Other lectures will be given Saturday at 8:30 in the Academy of Medicine, 17 West Forty-third street, as follows:

December 4.—Prof. Otto Cohnheim, University of Heidelberg, "The Influence of Sensory Impressions on Scientific Deductions."

December 11.—Prof. T. G. Brodie, University of Toronto, "Renal Activity."

December 18.—Prof. Carl G. Huber, University of Michigan, "Renal Structure."

Jan. 15, 1910.—Prof. Ludwig Hektoen, University of Chicago, "Certain Phases of the Formation of Antibodies."

February 19.—Dr. Eugene L. Opie, The Rockefeller Institute, "Inflammation."

March 5.—Prof. Adolf Meyer, Johns Hopkins University, "The Present Status of Aphasia and Its Relation to Psychopathology."

March 19.—Prof. A. Magnus-Levy, University of Berlin, "Pathology and Therapy in Diseases of Metabolism."

April.—Prof. Jules Bordet of the Pasteur Institute of Brussels. The exact date and title will be announced later.

NORTH DAKOTA

Personal.—Dr. Maude R. Williams has been elected secretary of the Health Reform Organization recently organized at Devils Lake.——Dr. Thomas M. MacLachlan, Bismarck, has resigned as physician to the Indian School.

Sanatorium Site Selected.—After several months' deliberation, the committee consisting of Drs. Gustave F. Ruediger, Grand Forks, James Grassick, Grand Forks, and Fannie Dunn Quain, Bismarck, appointed by the state legislature to select a site for a state sanatorium for tuberculosis, announces that it has selected a site 2½ miles north of Dunseith, on the south slope of Turtle Mountain. The state proposes to buy 160 acres if the town of Dunseith will furnish 80 acres additional.

District Society Organized.—As the result of the recent visit to Dickinson of Dr. J. N. McCormack, the Southwestern District Medical Society has been organized, with the following officers: President, Dr. Victor H. Stickney; vice-president, Dr. Homer A. Davis, and secretary, Dr. Joseph P. Weyrens, all of Dickinson.

OHIO

Defense Society Urged.—In order to protect the rights of the medical profession of the state from quacks, blackmailers, malpractice suits and other evils, the founding of a state defense organization was advocated at a meeting of the State Association of Secretaries of Medical Societies, held in Columbus recently.

Personal.—At the recent municipal election, Dr. Louis Schwab was elected mayor of Cincinnati, Dr. John M. Withrow, a member of the board of education at large, and Dr. Henry J. Cook, a member of the city council.——In a collision between automobiles at Cleveland, November 11, Dr. Willard C. Stoner was thrown from his auto and severely injured.

Hospital Staff Elected.—At a special meeting of the board of directors of the Cincinnati Hospital, the following staff was elected for the ensuing year:

Physicians East Medical Service: Drs. Edwin W. Mitchell and Frederick Forchheimer, seniors; Dr. Louis G. Heyn, junior.

Physicians West Medical Service: Drs. George A. Fackler and Oliver P. Holt, seniors; Dr. Allan Ramsey, junior.

Physicians South Medical Service: Drs. John E. Greiwe and Mark A. Brown, seniors; Dr. Henry L. Woodward, junior.

Neurologists: Drs. Herman H. Hoppe and Frank W. Langdon, seniors; Dr. Phillip Zenner, consultant, and Drs. Robert Ingram and David I. Wolfstein, juniors.

Surgeons: Drs. Joseph Ransohoff, Nathaniel P. Dandridge, Edward W. Walker, John C. Oliver, Horace J. Whitacre and Simon P. Kramer, seniors, and Drs. Casper F. Hegner, Arch I. Carson, Carl R. Hiller, Harry H. Hines and Frank E. Fee, juniors.

Orthopedic surgeons: Drs. Albert H. Freiberg and Charles E. Caldwell, seniors, and Dr. Robert Carothers, junior.

Dermatologists: Drs. Augustus A. Ravogli and Meyer L. Heidingsfeld, seniors, and Dr. Elmore B. Tauber, junior.

Oculists: Drs. Robert Sattler and Derrick T. Vail, seniors, and Dr. Victor Ray, junior.

Laryngologists and aurists: Drs. Samuel E. Allen and John W. Murphy, seniors.

Pediatrists: Drs. Allyn C. Poole and B. Knox Rachford, seniors, and Drs. Alfred Friedlander and Frederick W. Lamb, juniors.

Obstetricians: Drs. William D. Porter and George M. Allen, seniors, and Dr. Robert W. Thomas, junior.

Gynecologists: Drs. Charles A. L. Reed, Charles L. Bonifield, John M. Withrow and Sigmar Stark, seniors, and Dr. James W. Rowe, junior.

Pathologist: Dr. Paul G. Woolley.

Radiographer: Dr. Sidney Lang.

Cystoscopists: Drs. A. P. Cole and J. Louis Ransohoff.

Dentist: Dr. H. C. Matlack.

Laboratory and museum: Drs. W. E. Wherry, Frederick W. Lamb, Arthur E. Osmond, Charles S. Rockhill, Marion Whitacre, William H. Strictmann and A. P. Cole.

Anesthetist, with rank of junior, Dr. F. H. McMechan.

OREGON

Hospital for Wallowa.—At a mass meeting, November 4, in Wallowa, $3,000 of the $5,000 necessary to secure the building of a hospital in that city was subscribed. The institution will be in the charge of Dr. Verdo D. Gregory.

Free Dispensary to be Opened.—With the cooperation of the Oregon Medical College and Visiting Nurses' Association, the Peoples Institute has decided to open a free dispensary in rooms rented from the Men's Resort.

Personal.—Dr. Edwin E. Straw, mayor of Marshfield, was painfully injured in an automobile accident, October 10.——Dr. Jacob S. Giltner, Portland, sustained a third attack of paralysis, October 5.——Dr. Estelle J. Stinson, Portland, suffered a dislocation of the elbow, contusion of the shoulder and a severe cut on the face in a runaway accident recently.

PENNSYLVANIA

Ex-Residents' Association Election.—At the regular meeting of the Mount Sinai Hospital Ex-Residents' Association, held November 3, the following officers were elected for the term of one year: President, Dr. Maurice B. Cooperman; vice-president, Dr. Samuel Wexlar, and secretary and treasurer, Dr. Morris Ginsburg.

New Portrait for University Collection.—An addition has been made to the collection of oil portraits in the Medical Department of the University of Pennsylvania, a painting by Lazar Luditz of Dr. Hobart A. Hare, professor of children's diseases in the university in 1890-91. The collection of portraits of ex-professors in the medical department is complete with but ten exceptions and this number will shortly be reduced to seven, as the descendants of Dr. Adam Kuhn and Jacob Randolph have recently promised to present oil paintings of their ancestors, and Julian Story has almost completed the portrait of Dr. Samuel G. Dixon. Of the seven remaining ex-professors whose portraits are lacking, five are living, Drs. Billings, Starr, Flexner, Strawbridge and Kelly, while two are deceased, Drs. J. B. Rogers and John Carson.

State Hospitals Warned.—Heads of all the state hospitals for the insane were warned, November 15, by Auditor General Young that he would no longer honor bills for patients who were not actually being treated. It is said to have been the practice in many hospitals to allow patients to go out on parole and still to continue to carry the names on the records as being under the care and treatment of the institution.

Philadelphia

New Quarters for Pediatric Society.—The Philadelphia Pediatric Society announces that it has secured Thomson Hall in the new building of the College of Physicians, where all future meetings will be held.

New Home for Indigent.—On November 18, council's finance committee reported favorably an appropriation of $50,000 for the purchase of a site, containing forty-seven acres, known as the Holmesburg Driving Park. This is the first step toward building the new home for the city's poor. There is already available nearly $700,000 for the building. Before the plans are drawn Dr. Joseph S. Neff, director of health and charities, and the architect will consult with Homer Folk, president of the New York visiting committee of the New York State Aid Association.

Physicians Guests of Druggists.—The members of the Southwark Medical Society were the guests of the Southeastern Drug Association at a banquet, November 19. The speakers were Dr. Max Staller, president of the society, and Dr. Max Barbour. The latter spoke on "The Relation of the Physician to the Druggist."

GENERAL NEWS AND COMMENT

The "New" (?) Method of Spinal Anesthesia

Sensational reports of a remarkable new anesthetic and method of anesthesia have recently appeared in the newspapers. These reports, which would lead the reader to infer that this method had just been brought before the profession, refer to the method of spinal anesthesia with Jonnesco's modification, by which, through the addition of a small quantity of strychnin to the anesthetic (stovain) to overcome the toxic effects, he claims to be able to make the injection at any point of the spinal column, so as to secure complete general anesthesia.

Of course, spinal anesthesia has been in use for several years; and even the modification introduced by Jonnesco of Bucharest is not new, having been presented by him before the Second Congress of the International Society of Surgery, which met at Brussels in September, 1908. In conjunction with A. Jiano, Jonnesco also published his modification in the *Therapeutische Monatshefte*, May, 1909, and elsewhere. In the *Presse médicale*, Oct. 13, 1909, he published a full account of his methods and results. Briefly, his technic is as follows:

A quantity of stovain (tropocain or novocain), varying according to the patient and the height at which the puncture must be made, is placed in a sterilized rubber-stoppered tube. To this is added 1 c.c. of a solution containing from 0.5 to 1 mg. of strychnin sulphate in sterilized water. The puncture is made in one of two localities, between the first and second dorsal or between the twelfth dorsal and the first lumbar vertebræ, or both combined. For anesthesia of the head and neck, the patient lies with the head a little raised if the operation is to be made on the neck, or with the head horizontal if the operation is to be made on the face or skull. If the operation is on the arm, the patient remains sitting for two or three minutes and then lies with the head slightly raised. For operation on the abdominal viscera and the lower extremities, injection is made into the dorsal lumbar region and the patient is kept sitting for two or three minutes, after which he is allowed to lie with the shoulders raised.

Jonnesco claims to have had no fatalities and no mishaps during or after the anesthesia. In his view there are no contraindications and the anesthesia is always successful if the fluid has entered the subarachnoid space. Jonnesco asserts that the method is particularly advantageous for operations on the face and neck; also for laparotomies on account of the absolute immobility of the viscera and the freedom from coughing and vomiting. He says that in the hands of other surgeons his method has given favorable results, the total of cases in which this technic has been applied to July, 1909, amounting to 625. A tendency to nausea was noted in scarcely more than 2 per cent. of his cases; vomiting in 1.25 per cent.; sweating in 2 per cent.; slight headache, disappearing in a few hours, in 6.25 per cent., and retention of urine in 4.5 per cent., but only after operations in which this is usual under inhalation anesthesia. The pulse was generally normal, occasionally a little accelerated (80 or 90), but always strong, showing how the strychnin obviates the depressing action of the anesthetic. There was momentary arrest of respiration in five cases during Jonnesco's tentative experiments with atropin, scopolamin, etc., but none since he has been using the technic described. The anesthesia persists for from one and a half to two hours. Less than 0.1 gm. of stovain allows persistence of sensation of traction, but with this dose all sensation is abolished. Jonnesco adds that the strychnin and stovain must not be sterilized, as this impairs some of their properties.

At the meeting of the thirty-eighth congress of the German Society of Surgery at Berlin, April 14 to 17, Bier, in discussing spinal anesthesia, condemned the method of Jonnesco; and Rehn, at the same meeting, stated that if an anesthetic liquid is injected into the tissue of the medulla in animals, death occurs immediately, owing to a subacute intoxication by the medicament, for, Rehn says, death does not result if distilled water only be injected. This experiment, according to Rehn, shows the considerable danger of injections made above the lumbar region, as Jonnesco has recommended. Jonnesco's illustrated paper in the *Bull. de l'Acad. de Méd.*, Oct. 12, 1909, and in the *Presse médicale*, cited above, is in part a reply to these criticisms.

Southern Medical Association Meets.—The fourth annual convention of the Southern Medical Association was held in New Orleans, November 9-11, under the presidency of Dr. Giles C. Savage, Nashville. The annual oration was delivered by Dr. Isadore Dyer, New Orleans; the address in medicine by Dr. John A. Witherspoon, Nashville, Tenn.; the address in surgery by Dr. Francis G. DuBose, Selma, Ala., and the address in ophthalmology by Dr. Alexander W. Stirling, Atlanta, Ga. Dr. Witherspoon made a plea for the elimination of politics from medical boards, and urged the association to demand that the laws of the states included therein be so changed as to make it obligatory on the respective governors to select members of state boards of health from a list of competent physicians recommended by medical men. The following officers were elected: President, Dr. Walter W. Crawford, Hattiesburg, Miss.; vice-presidents, Drs. James F. McKinstry, Gainesville, Fla.; Waller S. Leathers, University, Miss.; Jacob R. Snyder, Birmingham, Ala.; H. L. Harris, Georgia; George Dock, New Orleans, and Frank A. Jones, Memphis, Tenn., and secretary-treasurer, Dr. Oscar Dowling, Shreveport, La. (reelected). Nashville was selected as next place of meeting. A resolution was introduced by Dr. Frederick J. Mayer, Scott, La., urging the clergy to unite with physicians in improving the sanitary conditions of the South, and that steps be taken to systematically collect vital statistics. Dr. E. Denegre Martin, New Orleans, introduced a resolution endorsing the movement for a national board of health. A resolution was adopted thanking John D. Rockefeller for his contribution of $1,000,000 to fight the hookworm disease. The medical section elected Dr. George Dock, New Orleans, chairman, and Dr. H. Eugene Mitchell, Birmingham, Ala., secretary. Dr. Urban S. Bird, Tampa, Fla., was elected chairman of the section on ophthalmology, and Dr. Edward C. Ellett, Memphis, Tenn., secretary. The surgical section elected Dr. E. Denegre Martin, New Orleans, chairman, and Dr. Jere L. Crook, Jackson, Tenn., secretary.

Plans and Suggestions for the Housing of Tuberculous Patients.—The National Association for the Study and Prevention of Tuberculosis, 105 East Twenty-second street, New York, has issued a pamphlet entitled "Some Suggestions and Plans for Housing Consumptives," containing views, floor plans and estimated cost of construction of cottages and sanatoriums of various types. The subjects considered are: the grouping of sanatorium buildings; administration buildings; the plan of combining administration buildings and patients' quarters under one roof (not recommended, except where economy in the remodeling of old buildings is the first consideration); the lean-to type of patients' quarters (recommended for cheapness of construction and as serviceable and comfortable when roughly finished for patients with incipient tuberculosis, and when well finished for patients with advanced tuberculosis); infirmaries and buildings for patients with advanced tuberculosis; the cottage type of building for one, two or more patients; remodeled farmhouses; day camps; and sleeping-porches for home treatment. The pamphlet embodies the preliminary report of the studies of Dr. Thomas Spees Carrington, who has by correspondence and personal investigation covered the entire field of the United States. The association has at its offices much more detailed data, architects' plans, drawings, etc., and invites correspondence with any one interested in the subject of sanatorium and hospital construction.

Sioux Valley Physicians to Meet.—The semi-annual meeting of the Sioux Valley Medical Association, whose membership is made up of physicians of Minnesota, South Dakota, Nebraska and Iowa, will be held in Sioux City, Iowa, January 20 and 21, under the presidency of Dr. Mathew N. Voldeng, Cherokee, Iowa. The program for the coming meeting is arranged with special reference to the interests of the general practitioner and internist.

Meeting of Southwestern District Medical Society.—At the fourth annual meeting of the Medical Association of the Southwest, held in San Antonio, Texas, November 9, 10 and 11, under the presidency of Dr. Jabez N. Jackson, Kansas City, Mo., the following officers were elected: President, Dr. George H. Moody, San Antonio, Texas; vice-presidents, Drs. Howard Hill, Kansas City, Mo., Charles E. Bowers, Wichita, Kan., David A. Myers, Lawton, Okla., and Asbury J. Vance, Harrison, Ark.; secretary-treasurer, Dr. Fred H. Clark, El Reno, Okla. (reelected); and executive committee, Drs. S. Grover Burnett, Kansas City, Mo., Jacob F. Gsell, Wichita, Kan., Everett S. Lain, Oklahoma City, Okla., James A. Foltz, Fort Smith, Ark., Edward H. Cary, Dallas, Texas, and Charles E. Bowers, Wichita, Kan. Wichita was selected as the place of next meeting.

The Ohio Valley Meeting.—The eleventh annual meeting of the Ohio Valley Medical Association was held in Evansville, Ind., November 10, 11 and 12, under the presidency of Dr. Curran Pope, Louisville, Ky. The following officers were elected: President, Dr. Albert E. Sterne, Indianapolis; vice-presidents, Drs. G. Frank Lydston, Chicago, William D. Haines, Cincinnati, and Louis D. Brose, Evansville, Ind., and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville, Ind. It was decided to hold the next meeting in Evansville.

Meeting of Railway Surgeons.—At the annual meeting of the Big Four Railroad Surgeons' Association in Indianapolis, November 4, the following officers were elected: Dr. John J. Kyle, Indianapolis, president; Drs. Charles K. Smith, Kankakee, Ill., Irvin J. Becknell, Goshen, Ind., and James T. Musselman, Paris, Ill., vice-presidents; and Dr. Thomas C. Kennedy, Shelbyville, Ind., secretary-treasurer.

LONDON LETTER

(From Our Regular Correspondent)

London, Nov. 13, 1909.

Exposure of a Notorious Quack

A notorious quack who described himself as "Dr. Walford Bodie, hypnotist, bloodless surgeon, etc.," has been effectually exposed in the law courts. The methods and success of this individual were extraordinary. He demonstrated (?) marvelous healing powers in cases of paralysis to the satisfaction of packed audiences at all the music halls of the country. Indeed from the theatrical point of view he was a "star" of the first magnitude, rivalling in attractive power the most talented artists of the variety stage. Attired in an academic costume with cap and gown he appeared on the stage and delivered a tirade against the medical profession and the hospitals and claimed to cure, by means of electricity, cases of paralysis which had been pronounced incurable. He announced that he knew that there were physicians and students in the audience from some well-known local hospital, such as St. Bartholomew's, who regarded his healing powers with jealousy. He evoked a cheer by challenging them to come on the stage and disprove anything he said. Then a number of patients were introduced for treatment. They were always carried on the stage, the lights were lowered, "Dr." Bodie performed passive movements of the joints of the paralyzed limb and then applied electricity from a battery, the lights were raised and the patient walked off the stage amidst applause. A farmer's son, who paid the quack $5,000 to teach him "bloodless surgery, hypnotism and medical electricity," was simply shown how the tricks were done. He sued for breach of contract. A boy, the subject of infantile paralysis, gave evidence that after he had been treated at two hospitals he saw "Dr." Bodie one morning at the Camberwell Music Hall. It was arranged that he was to come for the evening performance. He was not allowed to walk on the stage, although he could have done so. He was forced into a chair and carried on. He had never used crutches, but a pair were flung across the stage as though he had. "Dr." Bodie moved the limb about, applied the battery and then amid the applause of the audience led him off the stage. Another cripple who had to walk with sticks had his sticks broken before the audience and consequently had the greatest difficulty in getting home, even with the assistance of his mother and brother. A third was made to hold up a chair in sight of the audience as if he had been cured of paralysis of the arm, although only his legs were affected. In other cases the performance was given with the aid of confederates who paid for admission and pretended to be members of the audience. One was said by the "doctor" to be "suffering from catalepsy in a diseased form." The jury found that Bodie induced the plaintiff to enter into the agreement by fraudulent misrepresentations and awarded $5,000 damages.

The Cripples' Home and College at Alton

One of the most remarkable institutions founded in this country is the Cripples' Home and College which has recently been founded by one of the lord mayors of London, Sir William Treloar. It is situated on an estate of seventy acres in Hampshire and consists of wooden pavilions on brick piles connected by covered corridors. Not only is every provision made for the medical treatment of crippled children but also for their education and training in useful arts. There are carpenter, leather-bag and tailoring workshops in which sixty cripples are being trained. Two hundred children under 12 are being treated for active tuberculosis. It is now well recognized that the treatment of such cases in the hospitals of cities, whether as in- or out-patients, is most unsatisfactory. The greatest precautions are taken against the introduction of infectious diseases into the home by new patients. On admission the child's clothes are sterilized and the child is placed in quarantine for a fortnight in a glass cubicle. Most of the cases are tuberculous. The only other elements in the treatment which are regarded as important are diet and open air. Tuberculous abscesses are treated by aspiration under strict aseptic precautions and the results are much better than those of operation which often ends in septic infection. In the summer an open-air school is held in an adjoining forest for those children who can attend, on the lines of the forest school in Charlottenburg. There is also a college for a different purpose—the training in some trade of boys from the ages of 14 to 18 crippled from any cause. Those for whom an open-air life is especially suited learn poultry farming and horticulture. Others learn leather-working, cobbling and tailoring. A proposed extension of this work is the establishing of a self-supporting labor colony. All lads who can be benefited by drilling are drilled. Special exercises are employed in cases of scoliosis and other deformities.

The British Medical Journal's Attack on Nostrums

The *British Medical Journal* has republished in book form the series of articles which appeared in its columns, entitled, "Secret Remedies: What They Cost and What They Contain." The book has had a very large sale and already has had to be reprinted several times, although it has not been extensively advertised, and indeed some leading journals of the lay press have both declined advertisements of the book and also ignored copies that were sent for review. The reason, of course, is that nostrum mongers advertise heavily in the lay press and the papers in question are afraid of offending them. I pointed out previously that any attempt to deal with the nostrum evil would be resisted by several powerful forces, among which was the lay press. The papers which have refused the advertisements are otherwise highly respectable and profess to instruct their readers on everything under the sun but they now refuse to give them the only reliable information ever offered to the public on the highly vaunted remedies which occupy so much of their space. Of course nostrums of this class—infallible cures for consumption, rheumatism, cancer and other diseases—find no place in the advertising pages of the medical press. But it must be confessed that preparations of secret composition for which misleading claims are made, such as antikamnia, are advertised by some journals. Indeed, the cynic may amuse himself by reading in one English medical journal a series of articles denouncing nostrums and quackery of all sorts and finding in the advertising pages preparations of the antikamnia class. The majority of the preparations, however, advertised in the medical journals are produced on ethical lines and no recognized medical journal in this country is controlled by nostrum vendors. We have no journals of the class which exhausts vituperation in resisting the attempts of the Council on Pharmacy and Chemistry of the American Medical Association to deal with the nostrum evil and have the audacity to describe themselves as "independent" when they are dependent in the worst sense—dependent on the pay received for write-ups published to mislead the profession.

The Teaching of Therapeutics

At the Royal Society of Medicine, Prof. Clifford Allbutt opened an important discussion on the teaching of therapeutics in the hospital ward. He said that physicians must be pioneers and could not afford always to wait for the pharmacologists; but there must be mutual watchfulness of each other. Much that we know now to be good came from empirical knowledge and this was still going on, but our empiricism must be of the best, the knowledge of experience. He gave three examples of empirical knowledge which originally came from folk-medicine, and which has stood the test of modern research—digitalis, vaccination and poultices. The latter after suffering abuse had been shown by the work of Bier to be fundamentally reasonable. The student should be assured that apart from pharmacologic proof there was a large tradition of empirical knowledge of great value. He should be told that such and such are the means found useful in clinical experience whether they could be scientifically explained or not. They should go to the bedside as artists to do what good they could for the patient with such lights as they had. Finally, the student should be told he had to deal with living realities. He should be (1) no sceptic or he would endanger his own resourcefulness; (2)

given a clear idea of the *vis medicatrix naturæ*; (3) warned against the overuse of drugs and shown how closely therapeutics depend on prognosis. In the discussion which followed there was some divergence of opinion. Professor Osler described the methods adopted at the Johns Hopkins University and laid stress on their practical advantages. Dr. R. Hutchison relied more on teaching the student to be a sound diagnostician than a pharmacologist and suggested that the time was ripe for some agreement on the main lines of treatment to be adopted in certain well-known diseases, such as gastric ulcer. Dr. A. P. Beddard thought it was impossible to teach therapeutics in the wards.

The Falling Birth-Rate

The registrar-general's return for the quarter ending September again records a decreased birth-rate for England and Wales, the proportion being 25.4 annually, which is 2.5 below the average for the ten corresponding quarters and is the lowest for any third quarter of the year since the establishment of civil registration. On the other hand, the deaths were only 11.6 per 1,000, which was 3.4 below the average for the last ten years, and again the lowest on record for the period in question. Taking the two returns together, the natural increase in population by excess of births over deaths was 123,878, as against 123,197 in 1908. The low death rate is all the more remarkable, as the weather conditions have been unfavorable. The summer months included only one substantial spell of fine seasonable weather. Thanks to the great attention which is now being paid to infant hygiene, the mortality of infants under 1 year showed the large decrease of 38.6 per cent.

Deaths Due to Veronal

The public have no difficulty in obtaining hypnotic veronal in the form of tablets from the druggists. A considerable number of deaths following the use of the drug has now been recorded, and in several cases the dose taken was by no means large—10 or 15 grains. In one fatal case the subject, a well-known physician, the son-in-law of an eminent London surgeon, died in the prime of life.

Death of a Pathologist from Glanders Inoculation

The death at the early age of 30 years of Dr. John Herbert Wells, adds one more to the list of martyrs in the cause of scientific [illegible] reer of promise has been cut short. [illegible] imself in original research, Dr. Wells j[illegible] of therapeutic inoculation at St. Mary's Hospital, and in conjunction with the chief, Sir A. E. Wright, did valuable original work. In February, 1908, he began a research on the treatment of glanders, and the patient on whom his treatment was tried recovered, but in his laboratory work Dr. Wells had the misfortune to contract the disease. After eighteen months of suffering, he died, leaving a widow and two children unprovided for. An influential committee has been formed to collect a fund for their benefit.

The Fate of the Dolicho-Cephalic Blond Race

At the Royal Anthropological Institute of Great Britain, Professor Retzius of Stockholm delivered the Huxley lecture on "The Fate of the Dolicho-Cephalic Blond Race." The son of Anders Retzius, the founder of modern craniology, his lecture was worthy of his origin, and proved of great interest. He finds that 87 per cent. of the Swedes are long-headed and 73 per cent. have fair hair. These he regards as pure representatives of the North European race, which is still found in Scandinavia, North Germany and Britain, but from the earliest neolithic time spread widely over Europe. He regards them as the aborigines of Europe. Of their future, Professor Retzius takes a gloomy view. He thinks the qualities which made them great in the past unfit them for the life of industrial civilization. The round-headed, dark-haired race has supplanted them in central Europe by superior industrial qualities and threatens ultimately to overwhelm them.

Indian Conference on Malaria

The government of India proposes to form a permanent organization to inquire, systematically, into the problems, both practical and scientific, connected with malaria in India. It is estimated that over 1,000,000 deaths per annum occur from this disease. It has been decided to hold a conference in consultation with the administrative medical officers of the various provinces. Three groups of problems will be discussed: (1) The distribution of malaria in each province in relation to the sickness and mortality it produces; (2) measures of prevention which have been adopted in different provinces, such as drainage, mosquito destruction, and quinin distribution and their success or otherwise.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov. 4, 1909.

Association of the Members of the Faculties of the Medical Schools

The *Association des membres du corps enseignant des Facultés de médecine*, founded last spring (The Journal, April 10, 1909, lii, 1192; May 22, 1909, lii, 1676) held its second convention October 29 and 30 at the Paris school, under the presidency of Prof. J. Courmont of Lyons, assisted by Professors Reclus of Paris and Gross of Nancy. During four long meetings the delegates studied, article by article, the new ministerial project for reform of medical studies. The convention asked for the adoption of the principle sanctioning interchange of students between schools during the entire student period. The present regulations permit the student in his fifth year to study in a hospital either in a foreign country or in France, provided the necessary conditions are met. What is demanded now is that the student should be permitted to exchange one university for another during any of the years as is done abroad, especially in Germany, where the student has the privilege of taking parts of his course in the university which has the reputation of giving this part of the instruction best. The convention also considered the subject of practical instruction. Unfortunately, in the greater number of our university cities, especially in Paris, the hospitals belong not to the universities but to the public charities (*Assistance Publique*) and the latter sometimes adopt measures not favorable to instruction. Thus, a few years ago, the Public Charities of Paris made the dispensary consultations independent of the internal hospital service. The *stagiaire* students at the hospital are thus deprived of the possibility of seeing cases frequent in ordinary practice but not treated in hospitals. It is the universal opinion that the consultation is the place where students can get the best practical instruction. Doubtless the students might attend the dispensary consultation during a part of their period of hospital study, but in Paris, at least, these special consultation services are directed by the youngest members of the hospital staff, whose clinical experience hardly justifies entrusting them with the most difficult portion of practical instruction. Therefore, on the motion of Professor Delbet of Paris, the convention unanimously resolved that dispensary consultations should be organized supplementary to each clinical service.

The Next Congress of Practitioners

The Congresses of Practitioners, devoted exclusively to the discussion of questions of professional interest, constitute a novelty in the history of the French medical profession. The first of these congresses was held in Paris in 1907, the second in Lille in 1908, and the third will be held in Paris at the end of March, 1910. The approaching congress will carry on the campaign for the suppression of the illegal practice of medicine, and will also oppose the exploitation of physicians by mutual benefit societies. It will study the law on public health, the question of the reservation of the hospitals for the poor exclusively, and the relations of physicians with administrative bodies.

Depopulation in France

Statistics in regard to the fluctuation of population in France during the first semester of the present year have just been published. Here are the comparative figures of births and deaths for the first semester of the years 1908-1909:

	1909	1908
Births	398,710	411,402
Deaths	426,913	401,894

Thus the number of births has diminished by 12,692, and at the same time the number of deaths has increased by 25,019. The population of France has diminished by 28,203, figures representing the excess of deaths over births. Almost all the departments of France have contributed to this diminution of the population, but the excess of deaths over births has been particularly marked in the departments which contain large cities, as the departments of the Seine (Paris), Rhône (Lyons), Gironde (Bordeaux), Bouches-du-Rhône (Marseilles), Haute-Garonne (Toulouse), etc. Only in some departments of the north and west is an excess of births over deaths recorded.

The Oath of Hippocrates and Medical Ethics

Instruction in medical ethics being generally very imperfect, Dr. de Grissac believes that it would be advantageous to print on the first page of the thesis for the doctor's degree, the oath of Hippocrates, which sets forth all the principles of ethics, although in archaic form. The *Syndicat des médecins* *de la Seine* has resolved that the oath of Hippocrates be hereafter printed on the first page of all the theses for the degree of doctor in medicine presented before the French schools. At the Montpellier medical school it has been the traditional usage to print this oath at the end of the thesis.

Improvement of the Night Medical Service in Paris

In consequence of complaints which were recently made on the subject of the workings of our night medical service (The Journal, Oct. 9, 1909, liii, 1201) a measure to make it more prompt has just been adopted. The booths in the streets used as stations for cabs and automobiles will hereafter remain open permanently. The public will find there, at any hour, the necessary information in regard to the night medical service, as well as the names and addresses of the physicians, midwives and pharmacists charged with the night service. At these posts, a police assistant mounted on a bicycle will be especially charged with the duty of summoning and accompanying the physician or midwife to the home of the person requiring services.

Sale of Oysters

In view of numerous cases of typhoid fever apparently caused by the consumption of diseased oysters, M. Chéron, under-secretary of the navy, has just appointed a commission, presided over by the inspector-general of the fisheries, to prepare hygienic regulations for the oyster-farms authorized to furnish oysters for consumption.

Laboratory Alcohol and the Public Revenue

For some time a notice has been posted on the door of the laboratory of the Pasteur Institute calling attention to the fact that the cost of the alcohol used has been considerably increased by revenue duties, and requesting economy in its use. All scientific and charitable institutions are affected by the duty, which was imposed in view of certain abuses which have been shown in the institutions of two large provincial cities. It will entail a burdensome expense on our laboratories. The price of alcohol at 90 degrees is raised by it to 4 francs 50 centimes a liter (about $3.50 a gallon); that of absolute alcohol to 6 francs a liter (about $4.75 a gallon). There will be an annual increase of expense for the Pasteur Institute of more than 10,000 francs ($2,000).

Traumatic Tuberculosis and the Law on Industrial Accidents

At a recent session of the Academy of Medicine, Dr. Mosny, physician of the hospitals of Paris, presented a report on the relations between tuberculosis and industrial accidents, which often cause many difficulties in legal medicine. Dr. Mosny admits that the influence of industrial traumatisms on the outbreak, and the aggravation of tuberculous lesions may be manifested in various ways, so that from the point of view of the employer's responsibility, three types should be distinguished: 1. The tuberculosis has really been inoculated in the course of work as in the case of butchers, etc. It is then undeniably the direct and immediate consequence of the accident and full compensation should be allowed. 2. The tuberculosis, hitherto latent, has been fanned into flame again by a traumatism without which perhaps it would never have broken out. Mosny thinks that a traumatism capable of causing such consequences is a source of harm to the victim equalled by that which would be occasioned by actual infection with tuberculosis; in other words, the employer's responsibility should be considered as complete as in the first case. 3. The traumatism has created in the tuberculous subject a new focus or has aggravated preexisting lesions. In this case the indemnity should be limited to the difference existing between the previous salary and the smaller salary which the workman is capable of earning after the accident.

Etiology and Prophylaxis of Typhoid in France

At the same session of the Academy of Medicine, Dr. H. Vincent, professor in the school of military hygiene at Val-de-Grâce, called attention to the great frequency of typhoid fever in France. The proportion of deaths due to this disease is 27.6 per 100,000 inhabitants, while it is only 17.5 in England, 10.2 in the Netherlands and 10.3 in Germany. In the last seventeen years the number of typhoid deaths may be reckoned as about 100,000, the equivalent of the population of a large city. Moreover, this disease strikes down by preference young people, thus entailing very serious consequences from the demographic and economic point of view in a country with a low birth-rate like France.

Drinking water, foodstuffs soiled by flies, milk, oysters, sweet cider prepared with contaminated water, uncooked vegetables grown on ground fertilized by sewage, are important causes. The disposal of fecal matter in sewage-fields, practiced in many regions, is one of the causes which contribute most to the spread of typhoid fever. The discovery of chronic bacillus-carriers has thrown light on many apparently spontaneous cases of typhoid and paratyphoid. Dr. Vincent submitted a long program of antityphoid measures, comprising the following: popular elementary education of children and adults through physicians in regard to the nature of infectious diseases, the means of transmission and the prophylaxis; appointment of physicians as instructors of hygiene in the various departments of France; education of physicians to be specialists in hygiene, and special instruction in epidemiology in the medical schools; creation of schools of disinfection for the training of squads of disinfectors; organization of an increasing number of laboratories or stations of epidemiologic and bacteriologic research to aid in the battle against typhoid by bacteriologic investigation of suspected cases, by examination of bacillus-carriers; periodical examination of drinking-waters, etc. To these measures it is indispensable to add prohibition of the disposal of fecal matter in sewage-fields. In discussing Vincent's paper, Dr. Vallin remarked that typhoid fever is less frequent in the north of France, where beer is habitually drunk, than in the south, where water is used to dilute wine. Widal emphasized the importance of isolating typhoid patients in hospitals as cases of contagion in the wards are not infrequent.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov. 3, 1909.

The Imperial Association of German Physicians and the Imperial Insurance Bill

The counter organization to the Leipsic league which was founded a few months ago and which has assumed the haughty title of Imperial Association of German Physicians (*Reichsverband deutscher Aerzte*) has in the same way as the business committee of the German Medical Association (*Deutsche Aerztevereinsbund*) sent to the authorities a critique of the bill for an imperial insurance law in which naturally many demands are made which are in accord with the bill worked out by the government and are opposed to the demands of the medical association. Although the imperial association rejects the free choice of physician and wishes to leave the regulation of the medical system to a free agreement between the physicians concerned and the sick benefit societies (*Krankenkassen*), it does not differ from the medical association, for although the latter society wishes the free choice established, as a rule, it does not demand its compulsory introduction. While the medical association makes the demand that the insurance societies make the agreements as to the conditions of the contract only with the medical organizations, the imperial association wishes that such arrangements with private physicians be permitted as well.

This whole counter agitation is of little significance, as the imperial association comprises scarcely 2,000 members in contrast to the 24,000 members of the medical association.

Draft of New Penal Code

For some years there has been an urgent demand for a new penal code, since a number of the punishments imposed are antiquated. The draft of a new code elaborated by a commission of experts appointed by the government for this purpose has just appeared and contains a number of provisions that are of interest from their relation to sanitary matters. The age of criminal responsibility is advanced from 12 to 14 years. Confinement in an inebriate asylum can be ordered by the judge. A further provision against drunkenness is the possibility of forbidding the use of the saloon, and what is especially important, criminal responsibility for unconsciousness (*Bewusstlosigkeit*) as the result of voluntary inebriety, as well as for drunkenness dangerous to the general welfare. Discretion is given the judge to exempt from punishment in general those of defective responsibility. As a protection to the worker in dangerous trades special penalties are provided for removing or failing to provide protective devices. We will return to this important subject.

Personal

Professor Franz, the gynecologist of Jena, has been appointed as director of the gynecologic clinic at Göttingen as successor of Professor Runge.

Privy Councilor Dr. Wehmer, advisory physician to the Berlin police department, died October 31, at the age of 54, from heart failure, while riding his wheel. Wehmer had made himself a name in various branches of state medicine; he had devoted himself especially to the subjects of midwifery, school sanitation, and veterinary medicine. Among his important works we may mention: "The Sanitary Conditions of Berlin," "A Handbook of Public Health," "The Principles and an Encyclopedia of School Sanitation." Since 1897 he was president of the German Public Health Association of Berlin.

Full Time School Physicians

Three school physicians have been appointed for the evangelical schools of Chemnitz to devote their whole time to the work, beginning at Easter, 1910, at the salary of $1,750, to be increased to $2,250 (7,000 to 9,000 marks); in addition a pension is provided, but private practice is interdicted. Chemnitz has heretofore employed 17 school physicians on part time for its 34 schools with 42,000 pupils.

Monument for Fabricius von Hilden

The city authorities of Hilden (of the Rhine province) have determined to erect a monument to the famous seventeenth century surgeon, Fabricius von Hilden, who was born at that place, June 25, 1560. The unveiling is to occur in the summer of 1910, on the occasion of the three hundred and fiftieth anniversary of his birth. The city authorities have issued an appeal to all physicians for contributions.

Scarlet Fever Epidemic in Silesia

According to an official statement of the Silesian provincial medical board there have occurred in the district of Oppeln, since July 1, 2,200 cases of scarlet fever. By far the greatest number occurred in the industrial district of upper Silesia. In many localities the mortality reaches 30 per cent.

Cholera in East Prussia

The number of cholera cases in east Prussia has increased during the last week, but as before, the cases are sporadic.

Spinal Infantile Paralysis

Small epidemics of spinal infantile paralysis are now appearing in Silesia and in Mecklenburg. So far no fatal cases have been observed.

Tuberculosis Examinations by the Berlin Municipal Laboratory

The serious complaints that have been directed against our city government for the order described in the previous letter have borne fruit sooner than was to be expected. The administration has given notice that examinations of tuberculous material will be conducted also in the municipal laboratory free of cost. It would be very satisfactory if the administration on this occasion had announced a change in the policy maintained up to the present time and would pay more attention in future to the sanitary suggestions that are made by the medical profession.

German Institute for Medical Missions

A short time ago the German institute for medical missions was ceremoniously dedicated at Tübingen. This is an institution which has been established at the suggestion of the Stuttgart association for medical missions with the cooperation of all the evangelical missionary societies of Germany and Switzerland. The principal building furnishes accommodations for 32 students of medicine and missionaries. In addition there is a woman's building (*Schwesternheim*) that provides for 15 women medical students and future missionary midwives. In both houses there are for the inmates large society rooms, dining rooms, library, etc. The institute for medical missions is intended to make the students of medicine at the university of Tübingen and the members of the missionary societies acquainted with the requirements of the missionary service and in addition to give instruction in tropical hygiene and tropical medicine. For purposes of instruction, which is to be strictly scientific, it is planned to establish a clinic for tropical disease with the necessary laboratories at a cost of from $75,000 to $100,000 (300,000 to 400,000 marks). In order that no misuse of the knowledge obtained shall be made by those who are not physicians, every missionary who enters the institution must sign a statement that he will not use the knowledge and skill obtained for commercial purposes, and that he will not, on the ground of his education in this institution, style himself a missionary physician, and that he will not practice medicine at any time, either in Germany or other European countries, unless he has fulfilled the legal requirements of the individual nations. The medical education of the missionaries lasts one year, the students pay $87.50 (350 marks) for the summer semester, and $112.50 (450 marks) for the winter semester and missionaries pay for the year's instruction, $300 (1,200 marks).

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Nov. 6, 1909.

Investigations Into the Life of Medical Students

An interesting statistical research is just now going on in Vienna, the results of which are looked forward to with great eagerness by the circles interested in the outcome. Every medical student enlisting this winter term or the next (summer) term, at the Vienna University, will be asked to fill out a paper containing a series of questions: age, nationality, religion, language, financial position, previous education, and reasons for taking up medicine as a life-work. It is hoped that a large percentage of the students will take the slight trouble necessary to answer the questions. The student's name need not be given, only the initials. Separate lists will be kept for women. The only precaution taken is the earnest request to abstain from wilful misstatements.

As a rule medical students here belong to the poorer or at least not well-to-do classes of the population. Therefore, when once graduated they try to earn a living as quickly as possible, which explains why, generally speaking, medical fees in this country are much below English and American rates. Although warnings intended to stop the steady influx of new students to the profession have been published, the result has been inadequate. Therefore the investigators are directed also to find out why this special occupation was chosen by the individual.

Austrian Search for Scleroma

By an order of the ministry of the interior, all health officers are henceforth bound to report every case of rhinoscleroma to the ministry. For this purpose, a short description of the clinical symptoms, the histopathology and the geographical regions where it is found is furnished. Only a narrow strip of land bordering on Hungary and Russia, and part of the empire between Italy and Hungary may be looked on as a focus of infection. Altogether, there are about 320 cases now under observation, but without doubt, the actual number of persons afflicted is much larger. The order is partly an outcome of the last medical congress, partly the result of the work of the new health department, which in a remarkably progressive way tries to keep abreast of the advances in the science of hygiene.

Sale of Radium Salt

The production of radium has been carried on in Johannistal to such a degree that at present there is available a quantity equivalent to 1 gm. (15 grains) of the pure substance. Several tons of the ore had to be worked up before an appreciable amount was obtained. It is intended now to put the available quantity on the market solely for scientific purposes and for charitable institutions. It will be sold in quantities of 1 mg. (about 1/60 grain) of the 5 per cent. and the 10 per cent. salt. Bromid of radium has been chosen. The price of the 5 per cent. salt will be 1080 crowns ($244) per portion (1/60 grain). The sale will take place in the radium institute just now in course of erection. A magnificent gift by an anonymous benefactor, who gave $100,000 for this purpose on the understanding that an equal sum should be provided by the state, enabled the Vienna University to obtain its radium research institute, the first in the world as regards equipment for investigators. The necessary appropriation having been voted, the building is now almost ready for use.

Death of Professor Monti

By the death of Professor Monti, which took place during the last days of October, the Vienna medical faculty loses one of its best known and most honored members. He was a specialist in diseases of the children, and one of the founders and the director of the Vienna Poliklinik, where he was the head of the pediatric department. His courses were much frequented by Americans. He was the initiator of the "childrens' homes" in this country, and the convalescent homes on the Austrian coast of the Adriatic Sea were altogether the result of his strenuous effort. His merits were recognized by the emperor, who not only selected him as physician for his numerous grandchildren, but also conferred on him the title of *Hofrath* (court councilor). The contributions of the deceased physician to medical literature were not very numerous, his work having been chiefly practical and arduous endeavors to raise the standard of health and of feeding among the offspring of the poorest. His death will be sincerely lamented by many thousands of grateful patients and friends.

Pharmacology

ECHINACEA CONSIDERED VALUELESS

Report of the Council on Pharmacy and Chemistry

The Council has voted to reject several non-proprietary articles and has recommended that the reasons for their rejection be given in The Journal; among these is echinacea. The following paper has been submitted by a subcommittee with the recommendation that it be published. This recommendation was adopted.

W. A. Puckner, Secretary.

ECHINACEA

When this drug was first introduced, it was a typical nostrum, with exaggerations regarding its therapeutic value that were somewhat more gross than usual. It was later adopted by the eclectic school without being freed from the stigmata of its origin. It was also pressed into use as the main ingredient of such proprietary preparations as echafolta, ecthol, eusoma, etc. Efforts have been made to get the regular profession to use it in these various forms.

According to J. U. Lloyd (*Pharm. Review*, vol. xxii, p. 9-14), the introduction of echinacea into eclectic medicine is due to the efforts of Dr. H. F. C. Meyer to increase the sale of Meyer's Blood Purifier, a secret remedy containing it. The following is a literal copy of the label on this nostrum:

> MEYER'S BLOOD PURIFIER
>
> DIRECTIONS
>
> Take one ounce three times every day in the following cases: *Rheumatism, Sick Headache, Erysipelas, Dyspepsia, Old Sores* and *Biles, Open Wounds, Dizziness, Scrofula* and *Sore Eyes.*
>
> In case of *Poisoning by Herbs, & C.*, take the double dosis, and *Bites of Rattlesnakes* take three ounces three times a day, until the swelling is gone. This is an absolute cure within 24 hours.

After Lloyd had identified the plant, Meyer put the preparation out under another form with the following label:

> ECHINACEA ANGUSTEFOLIA
>
> This is a powerful drug as an Alterative and Antiseptic in all tumorous and Syphilitic indications; old chronic wounds, such as fever sores, old ulcers, Carbuncles, Piles, eczema, wet or dry, can be cured quick and active; also Erysipelas. It will not fail in Gangrene. In fever it is a specific; typhoid can be adverted in two to three days; also in Malaria, Malignant, Remittent and Mountain fever it is a specific. It relieves pain, swelling and inflammation, by local use, internal and external. It has not and will not fail to cure Diphtheria quick. It cures bites from the bee to the rattlesnake, it is a specific. Has been tested in more than fifty cases of mad dog bites in human and in every case it prevented hydrophobia. It has cured hydrophobia. It is perfectly harmless, internal and external.
>
> Dose.—One half to one fluid-drachm 3 or 4 times a day.
>
> Manufactured by H. C. F. Meyer, M.D.
>
> Price, $ Pawnee City, Neb., U. S. A.
>
> Patent

These absurd claims of an evidently ignorant man have passed into the more recent proprietary advertising matters
and into muc[illegible] the eclectic writings. Indeed, the seemingly
impossible ha[illegible] attained by even surpassing Meyer's all-
but-all-embrac[illegible] N[illegible] ent with endorsing echinacea
as a positive [illegible] for rattlesnake bite, syph-
ilis, typhoid fe[illegible] and hydrophobia, later
enthusiasts ha[illegible] lly certain curative
effects in tuber[illegible] thalmic goiter, and
with the power [illegible] t of cancer.

It is worth [illegible] surprising—
that these far-re[illegible] no better
than that of [illegible] who have
[illegible] erwise achi[illegible] te, dis-
[illegible] g and r[illegible] to
made tc [illegible] e
[illegible] d

e.
st
mu
C. S.

Eusoma Pharmaceutical Company), complains that he has been unable to interest regular physicians in the remedy. He reviews the statements of previous authors and reports eight cases of infection, only two being acute or extensive, in which he used it with asserted success.

In view of the lack of any scientific scrutiny of the claims made for it, echinacea is deemed unworthy of further consideration until more reliable evidence is presented in its favor.

FALSE UNICORN (HELONIAS)

Report of the Council on Pharmacy and Chemistry

The Council voted to refuse to recognize false unicorn as a non-proprietary article and the following statements, submitted by a subcommittee, were ordered published.

W. A. Puckner, Secretary.

FALSE UNICORN—HELONIAS

Helonias dioica, or more properly *Chamælirium luteum*, is a plant, preparations of which enter into various proprietary mixtures for diseases of the female pelvic organs. In the advertisements of these preparations it is usually credited with hemostatic powers and is asserted to be a uterine tonic.

There is practically no reference to this drug in reliable medical literature, and as there is no evidence worthy of credence to support the claims made for it, the drug was not considered deserving of a place in the Pharmacopeia. Hence, it may be regarded as a drug not worthy of attention of physicians.

Correspondence

Microscopic Moving Pictures

To the Editor: In the daily papers there have recently appeared items to the effect that Jean Commandon, a French scientist, has demonstrated in Paris in the presence of the members of the Academy of Science, his most wonderful invention, the microcinematograph, a machine which enables him to take moving pictures of microscopic objects and project them in motion on the screen. The New York *World* of October 31 says:

> "No longer is it possible for a bacillus, however microscopic, to live and move secretly. At last the intimate existence of an active microbe has been betrayed by the cinematograph . . . With this new instrument living organisms one thousandth of a millimeter in diameter are photographed and magnified, and can be studied . . . Professor Daster, an eminent bacteriologist, says it is impossible to estimate the importance of this advance in science, which opens a new world to the human eye, and reveals facts about minutest organism hitherto unsuspected."

I desire to call attention to the fact that this invention is nothing new; that the idea of such a machine was conceived by me some fourteen or fifteen years ago, *and that I demonstrated it*, after the construction has been completed, as far back as 1897, in my private office in the presence of Dr. Wm. H. Katzenbach, Dr. E. Bradley, Dr. Goodwille, Mr. David St. Clair, and others of prominence.

After this demonstration took place, the "micromotoscope," as I named the machine, was described in the *Scientific American*, July 31, 1897, from which the following is quoted:

> "The principles of the ki[illegible] have been applied
> to the microscope with so[illegible] by Dr. Robert L.
> Watkins of this city. Th[illegible] imple, was made
> success only after many [illegible] in adjusting the
> ective of the microscope [illegible] sort of light and
> rapidly moving film . . . This machinery is turned by a
> and its ordinary capacity is about 1,600 pictures per
> . . . The advantages of the microscopic photography to
> opy are evident, especially as regards the action of bacteria
> od cells . . . Numerous photographs of bacteria were
> but the motion happened to be an up-and-down one and
> no change of position in the field."

The same year (1897) the micromotoscope was again described and illustrated in *Photograms*, a London periodical, which said: "During the year two distinct steps have been made in kinematography"; then, after giving a description of Dr. Macintyre's invention in radiography, the editor proceeded:

> "Dr. Watkins, on the other hand, combined kinetography and photomicrography, so as to be able to record and reproduce the movements of objects so small as corpuscles, rotifers, microbes. This power of studying the motion of the corpuscles is expected to prove of infinite value in the diagnosis of certain diseases. From this it will be seen that kinetography, which commenced as a scientific industry, has made distinct steps in scientific progress, in addition to captivating the public taste . . ."

Not only was credit given me in the periodicals quoted above, but the "Standard Dictionary," 1905 edition, in defining the micromotoscope, refers to me as its inventor.

At about 1898, I again demonstrated this machine to a private audience at my house in the presence of Mr. Hopkins, editor of the *Scientific American*, Dr. G. L. Curtis, Dr. Fitch, Dr. J. H. Gunning, Mr. Robert Niles, and a few others of this city.

With the assistance of Mr. Thomas F. Livingston and Mr. E. W. Clausing, the micromotoscope was also shown at the Grand Central Palace of this city in the fall of 1897 at the Trained Nurses' and Pure Food Exhibition. Numerous microscopic objects, taken with the micromotoscope, were projected on the screen at this exhibition. Among others were the circulation of the blood in the web of the frog's foot, rotifers in stagnant Croton water, an ameboid leucocyte, moving blood-cells under the microscope, moving germs in fermenting urine, micrococci and bacteria, etc. Some of these positives were printed in the Edison Laboratory, East Orange, N. J.

At the time of this exhibition Dr. F. M. Jeffries of the New York Polyclinic furnished me with some specimens of typhoid germs, of which I made micromotoscope negatives. The above pictures were shown to over 10,000 people; one night these photographs were thrown right across the length of the immense main hall, producing a magnification of about 1,500,000 diameters, according to our rough figures. Some of the microscopic objects looked like "whales and sea-serpents," as some in the audience observed. Charles L. Bristol, Professor of Biology in the New York University, remarked at the time that he had not supposed that this could be done.

Mr. F. M. Ramsden of Santiago, Cuba, who was very much interested in this scientific achievement, is in the possession of the only photograph I took of my first micromotoscope outfit in position ready to work. The first pictures that were taken by it were specially mounted for and presented to Dr. Abraham Jacobi, who now has them, and who readily remembered it, when I mentioned the fact to him a few days ago.

Since this first outfit, I have gradually improved my camera, making it more simple, until I have at last produced the unique machine which I am now using. In experimenting on this micromotoscope, I have used up enough machinery and material to fill up a good-sized junk-shop.

The latest demonstration of the last pictures taken with this machine took place in Chicago on June 17 of this year, where I showed it to an audience of 500 doctors of the National Eclectic Association. Had I not been delayed with the construction of my new projecting machine, a demonstration of the micromotoscope would have taken place at the American Medical Association meeting in Atlantic City, last June.

I can cite many more instances to prove the validity of my claim of being the first to conceive this idea and demonstrate with a machine and photographs. The credit, then, for this invention rightly belongs to an American and not to a Frenchman.

Robert L. Watkins, M.D., New York.

Free Use of the Mails for Literature on Public Health

To the Editor:—About two years ago an effort was made by the state health officer of Florida to obtain for the various State and Territorial boards of health of the United States the privilege of free service through the mails for the distribution within State and Territory lines of sanitary and health bulletins and matters connected therewith. The measure was formulated into House Bill No. 11,317 and introduced by Hon. S. M. Sparkman, representative from the First Congressional District of Florida. When this measure was first proposed, the state health officer of Florida wrote to every State and Territorial board of health asking their cooperation through their representatives in Congress. Encouraging replies were received from all. It was hoped that the measure would become a law, especially since Mr. Sparkman received decided encouragement in his interview on the subject with the Postmaster-General. Later on, however, Mr. Sparkman was informed that President Roosevelt opposed the granting of this privilege; hence, of course, it was useless to proceed further with the measure.

The bill, as introduced, read as follows:

A BILL

II. R. 11317.

To extend the franking privilege to literature published by boards of health of states, territories, and municipalities in the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That it shall be lawful to transmit through the mails, free of *postage, any printed letters circulars, documents, pamphlets, and* literature relating exclusively to the public health, which shall be issued by or under the authority of any board of health of any state, territory or city in the United States.

Sec. 2. That every such letter or package to entitle it to pass free shall bear over the words "Public Health Business" an indorsement showing the name of the state, territorial or municipal board of health, as the case may be, whence transmitted. And if any person shall make use of any such official envelope to avoid the payment of postage on his private letter, package or other matter in the mail, the person so offending shall be deemed guilty of a misdemeanor and subject to a fine of three hundred dollars, to be prosecuted in any court of competent jurisdiction.

Now, there seems to be no good reason why the United States mails should not be made a medium for disseminating useful and instructive sanitary information to the people. Measures taken to inform the general public on questions relating to their health and life seem as important as political documents—to the mind of every intelligent citizen even more so; certainly capable of favorable comparison with the instance reported in the public press of "the franking of a set of furniture through the mails by a representative in Congress from his home at Washington when near the completion of his term of office."

This matter is now submitted to the medical profession and the health officials of the United States with the hope that they may approve the measure, give it strong endorsement to congressional delegations from each state of the union, and urge it with all fervency as an appeal to benefit humanity and to increase the life tenure of the citizen.

Joseph Y. Porter, Key West, Fla.,
State Health Officer of Florida.

Ability, the Real Test

To the Editor: There is a tendency on the part of the embryonic medical practitioner to become imbued with the foolish idea, after he has formally done with the state medical examining board, and procured a license to practice the healing art, that the public cares only to know that he has spent so many years in the high school, so many years in the academy, so many years in the college of liberal arts, so many years in the medical department of some university, and so much time as an intern.

The length of time spent in a college, or a dozen colleges, is no guarantee of knowledge acquired, nor is it a gage by which the public may reckon the fitness of a man to practice the principles of the craft. In fact, years have nothing to do with gaging the mental capacities of men. Men's mental abilities vary. Man's individual ability is as varied as his undertakings, and he achieves the really great things only after he has tried himself out. Therefore, there should be but one test—the test of ability, not the test of time as spaced off by college men. Nor is this statement intended to cast any reflections whatever on those who are engaged in the teaching of medicine.

Avoid the exaggeration, and remember this: the public cares little how long we have studied a particular subject, but rather how much we know of it!

Clyde A. Henry, M.D., Farson, Iowa.

Pharmacology

ECHINACEA CONSIDERED VALUELESS

Report of the Council on Pharmacy and Chemistry

The Council has voted to reject several non-proprietary articles and has recommended that the reasons for their rejection be given in THE JOURNAL; among these is echinacea. The following paper has been submitted by a subcommittee with the recommendation that it be published. This recommendation was adopted.

W. A. PUCKNER, Secretary.

ECHINACEA

When this drug was first introduced, it was a typical nostrum, with exaggerations regarding its therapeutic value that were somewhat more gross than usual. It was later adopted by the eclectic school without being freed from the stigmata of its origin. It was also pressed into use as the main ingredient of such proprietary preparations as echafolta, ecthol, eusoma, etc. Efforts have been made to get the regular profession to use it in these various forms.

According to J. U. Lloyd (*Pharm. Review*, vol. xxii, p. 9-14), the introduction of echinacea into eclectic medicine is due to the efforts of Dr. H. F. C. Meyer to increase the sale of Meyer's Blood Purifier, a secret remedy containing it. The following is a literal copy of the label on this nostrum:

> MEYER'S BLOOD PURIFIER
>
> DIRECTIONS
>

After Lloyd had identified the plant, Meyer put the preparation out under another form with the following label:

> ECHINACEA ANGUSTEFOLIA
>
> This is a powerful drug as an Alterative and Antiseptic in all tumorous and Syphilitic indications; old chronic wounds, such as fever sores, old ulcers, Carbuncles, Piles, eczema, wet or dry, can be cured quick and active; also Erysipelas. It will not fail in Gangrene. In fever it is a specific; typhoid can be adverted in two to three days; also in Malaria, Malignant, Remittent and Mountain fever it is a specific. It relieves pain, swelling and inflammation, by local use, internal and external. It has not and will not fail to cure Diphtheria quick. It cures bites from the bee to the rattlesnake, it is a specific. Has been tested in more than fifty cases of mad dog bites in human and in every case it prevented hydrophobia. It has cured hydrophobia. It is perfectly harmless, internal and external.
>
> Dose.—One half to one fluid-drachm 3 or 4 times a day.
> Manufactured by H. C. F. Meyer, M.D.
> PRICE, $ PAWNEE CITY, NEB., U. S. A.
> Patent

These absurd claims of an evidently ignorant man have passed into the more recent proprietary advertising matters and into much of the eclectic writings. Indeed, the seemingly impossible has been attained by even surpassing Meyer's all-but-all-embracing claims. Not content with endorsing echinacea as a positive and speedy "specific" for rattlesnake bite, syphilis, typhoid fever, malaria, diphtheria and hydrophobia, later enthusiasts have credited it with equally certain curative effects in tuberculosis, tetanus and exophthalmic goiter, and with the power of retarding the development of cancer.

It is worth noticing—although it is not surprising—that these far-reaching claims have been made on no better basis than that of clinical trials by unknown men who have not otherwise achieved any general reputation as acute, discriminating and reliable observers. No attempt seems to have been made to verify these claims by accurate scientific methods, clinical or otherwise, although this could very easily have been done.

Not one of the eulogistic reporters and exploiters seems to have considered it worth while to determine by the simplest control experiments whether the drug possesses any bactericidal or antiseptic powers whatever. It is therefore not very strange that discriminating physicians have failed to show much enthusiasm. One of the warmest endorsers of echinacea, C. S. Chamberlain (who later became the president of the Eusoma Pharmaceutical Company), complains that he has been unable to interest regular physicians in the remedy. He reviews the statements of previous authors and reports eight cases of infection, only two being acute or extensive, in which he used it with asserted success.

In view of the lack of any scientific scrutiny of the claims made for it, echinacea is deemed unworthy of further consideration until more reliable evidence is presented in its favor.

FALSE UNICORN (HELONIAS)

Report of the Council on Pharmacy and Chemistry

The Council voted to refuse to recognize false unicorn as a non-proprietary article and the following statements, submitted by a subcommittee, were ordered published.

W. A. PUCKNER, Secretary.

FALSE UNICORN—HELONIAS

Helonias dioica, or more properly *Chamælirium luteum*, is a plant, preparations of which enter into various proprietary mixtures for diseases of the female pelvic organs. In the advertisements of these preparations it is usually credited with hemostatic powers and is asserted to be a uterine tonic.

There is practically no reference to this drug in reliable medical literature, and as there is no evidence worthy of credence to support the claims made for it, the drug was not considered deserving of a place in the Pharmacopeia. Hence, it may be regarded as a drug not worthy of attention of physicians.

Correspondence

Microscopic Moving Pictures

To the Editor: In the daily papers there have recently appeared items to the effect that Jean Commandon, a French scientist, has demonstrated in Paris in the presence of the members of the Academy of Science, his most wonderful invention, the microcinematograph, a machine which enables him to take moving pictures of microscopic objects and project them in motion on the screen. The New York *World* of October 31 says:

> "No longer is it possible for a bacillus, however microscopic, to live and move secretly. At last the intimate existence of an active microbe has been betrayed by the cinematograph . . . With this new instrument living organisms one thousandth of a millimeter in diameter are photographed and magnified, and can be studied . . . Professor Daster, an eminent bacteriologist, says it is impossible to estimate the importance of this advance in science, which opens a new world to the human eye, and reveals facts about minutest organism hitherto unsuspected."

I desire to call attention to the fact that this invention is nothing new; that the idea of such a machine was conceived by me some fourteen or fifteen years ago, and that I demonstrated it, after the construction has been completed, as far back as 1897, in my private office in the presence of Dr. Wm. H. Katzenbach, Dr. E. Bradley, Dr. Goodwille, Mr. David St. Clair, and others of prominence.

After this demonstration took place, the "micromotoscope," as I named the machine, was described in the *Scientific American*, July 31, 1897, from which the following is quoted:

> "The principles of the kinetoscope or mutoscope have been applied to the microscope with some interesting results by Dr. Robert L. Watkins of this city. The instrument, though simple, was made a success only after many experiments and failures in adjusting the objective of the microscope in a line with the right sort of light and a rapidly moving film . . . This machinery is turned by a crank and its ordinary capacity is about 1,600 pictures per minute . . . The advantages of the microscopic photography to microscopy are evident, especially as regards the action of bacteria and blood cells . . . Numerous photographs of bacteria were taken, but the motion happened to be an up-and-down one and showed no change of position in the field."

The same year (1897) the micromotoscope was again described and illustrated in *Photograms*, a London periodical, which said: "During the year two distinct steps have been made in kinematography"; then, after giving a description of Dr. Macintyre's invention in radiography, the editor proceeded:

> "Dr. Watkins, on the other hand, combined kinetography and photomicrography, so as to be able to record and reproduce the movements of objects so small as corpuscles, rotifers, microbes. This power of studying the motion of the corpuscles is expected to prove of infinite value in the diagnosis of certain diseases. From this it will be seen that kinetography, which commenced as a scientific industry, has made distinct steps in scientific progress, in addition to captivating the public taste . . ."

Not only was credit given me in the periodicals quoted above, but the "Standard Dictionary," 1905 edition, in defining the micromotoscope, refers to me as its inventor.

At about 1898, I again demonstrated this machine to a private audience at my house in the presence of Mr. Hopkins, editor of the *Scientific American*, Dr. G. L. Curtis, Dr. Fitch, Dr. J. H. Gunning, Mr. Robert Niles, and a few others of this city.

With the assistance of Mr. Thomas F. Livingston and Mr. E. W. Clausing, the micromotoscope was also shown at the Grand Central Palace of this city in the fall of 1897 at the Trained Nurses' and Pure Food Exhibition. Numerous microscopic objects, taken with the micromotoscope, were projected on the screen at this exhibition. Among others were the circulation of the blood in the web of the frog's foot, rotifers in stagnant Croton water, an ameboid leucocyte, moving blood-cells under the microscope, moving germs in fermenting urine, micrococci and bacteria, etc. Some of these positives were printed in the Edison Laboratory, East Orange, N. J.

At the time of this exhibition Dr. F. M. Jeffries of the New York Polyclinic furnished me with some specimens of typhoid germs, of which I made micromotoscope negatives. The above pictures were shown to over 10,000 people; one night these photographs were thrown right across the length of the immense main hall, producing a magnification of about 1,500,000 diameters, according to our rough figures. Some of the microscopic objects looked like "whales and sea-serpents," as some in the audience observed. Charles L. Bristol, Professor of Biology in the New York University, remarked at the time that he had not supposed that this could be done.

Mr. F. M. Ramsden of Santiago, Cuba, who was very much interested in this scientific achievement, is in the possession of the only photograph I took of my first micromotoscope outfit in position ready to work. The first pictures that were taken by it were specially mounted for and presented to Dr. Abraham Jacobi, who now has them, and who readily remembered it, when I mentioned the fact to him a few days ago.

Since this first outfit, I have gradually improved my camera, making it more simple, until I have at last produced the unique machine which I am now using. In experimenting on this micromotoscope, I have used up enough machinery and material to fill up a good-sized junk-shop.

The latest demonstration of the last pictures taken with this machine took place in Chicago on June 17 of this year, where I showed it to an audience of 500 doctors of the National Eclectic Association. Had I not been delayed with the construction of my new projecting machine, a demonstration of the micromotoscope would have taken place at the American Medical Association meeting in Atlantic City, last June.

I can cite many more instances to prove the validity of my claim of being the first to conceive this idea and demonstrate with a machine and photographs. The credit, then, for this invention rightly belongs to an American and not to a Frenchman.

Robert L. Watkins, M.D., New York.

Free Use of the Mails for Literature on Public Health

To the Editor:—About two years ago an effort was made by the state health officer of Florida to obtain for the various State and Territorial boards of health of the United States the privilege of free service through the mails for the distribution within State and Territory lines of sanitary and health bulletins and matters connected therewith. The measure was formulated into House Bill No. 11,317 and introduced by Hon. S. M. Sparkman, representative from the First Congressional District of Florida. When this measure was first proposed, the state health officer of Florida wrote to every State and Territorial board of health asking their cooperation through their representatives in Congress. Encouraging replies were received from all. It was hoped that the measure would become a law, especially since Mr. Sparkman received decided encouragement in his interview on the subject with the Postmaster-General. Later on, however, Mr. Sparkman was informed that President Roosevelt opposed the granting of this privilege; hence, of course, it was useless to proceed further with the measure.

The bill, as introduced, read as follows:

A BILL

H. R. 11317.

To extend the franking privilege to literature published by boards of health of states, territories, and municipalities in the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

That it shall be lawful to transmit through the mails, free of postage, any printed letters circulars, documents, pamphlets, and literature relating exclusively to the public health, which shall be issued by or under the authority of any board of health of any state, territory or city in the United States.

Sec. 2. That every such letter or package to entitle it to pass free shall bear over the words "Public Health Business" an indorsement showing the name of the state, territorial or municipal board of health, as the case may be, whence transmitted. And if any person shall make use of any such official envelope to avoid the payment of postage on his private letter, package or other matter in the mail, the person so offending shall be deemed guilty of a misdemeanor and subject to a fine of three hundred dollars, to be prosecuted in any court of competent jurisdiction.

Now, there seems to be no good reason why the United States mails should not be made a medium for disseminating useful and instructive sanitary information to the people. Measures taken to inform the general public on questions relating to their health and life seem as important as political documents—to the mind of every intelligent citizen even more so; certainly capable of favorable comparison with the instance reported in the public press of "the franking of a set of furniture through the mails by a representative in Congress from his home at Washington when near the completion of his term of office."

This matter is now submitted to the medical profession and the health officials of the United States with the hope that they may approve the measure, give it strong endorsement to congressional delegations from each state of the union, and urge it with all fervency as an appeal to benefit humanity and to increase the life tenure of the citizen.

Joseph Y. Porter, Key West, Fla.,
State Health Officer of Florida.

Ability, the Real Test

To the Editor: There is a tendency on the part of the embryonic medical practitioner to become imbued with the foolish idea, after he has formally done with the state medical examining board, and procured a license to practice the healing art, that the public cares only to know that he has spent so many years in the high school, so many years in the academy, so many years in the college of liberal arts, so many years in the medical department of some university, and so much time as an intern.

The length of time spent in a college, or a dozen colleges, is *no guarantee of knowledge acquired*, nor is it a gage by which the public may reckon the fitness of a man to practice the principles of the craft. In fact, years have nothing to do with gaging the mental capacities of men. Men's mental abilities vary. Man's individual ability is as varied as his undertakings, and he achieves the really great things only after he has tried himself out. Therefore, there should be but one test—the test of ability, not the test of time as spaced off by college men. Nor is this statement intended to cast any reflections whatever on those who are engaged in the teaching of medicine.

Avoid the exaggeration, and remember this: the public cares little how long we have studied a particular subject, but rather how much we know of it!

Clyde A. Henry, M.D., Farson, Iowa.

The Attempt to Degrade the Sanitary Service at the Isthmus

The following correspondence, which explains itself, is commented on editorially in this issue:

Hon. James R. Mann:

Dear Sir: The attention of the Committee on Medical Legislation of the American Medical Association has been called to H. R. 5155, introduced by you in the House of Representatives, providing for the government of the Canal Zone and the construction of the Panama Canal. An examination of the bill shows that in Section 3, providing for the organization of the canal board, no provision is made for a chief sanitary officer of the same rank as the director, chief engineer and governor. The result of the adoption of the bill in its present form would evidently be the subordination of the sanitary department to the position which it occupied under the first canal board. I am sure that this was not your intention, in view of the great importance of the sanitary department in making the construction of the canal possible. In other words, I am confident that the omission of such a provision is an oversight. I therefore take the liberty of calling your attention to it and shall be glad to learn whether it would not be possible to amend the bill so as to leave the position of the sanitary department unchanged. I shall be very glad to hear from you on this point.

FREDERICK R. GREEN,
Secretary, Committee on Medical Legislation.

HOUSE OF REPRESENTATIVES
COMMITTEE ON INTERSTATE AND FOREIGN COMMERCE

Dr. Frederick R. Green, Chicago:

Dear Sir: Replying to your recent favor, I beg to say that I am not in favor of making a chief sanitary officer on the Canal Zone of the same rank as the chief engineer. It is not possible to have good government on the zone with a lot of different heads, but under the bill which I introduced the President has full authority to continue the Chief Sanitary Officer and give him as much authority as he now has. It would be impossible to carry on the work of the canal without constant friction if your sugestion was incorporated in the law and I trust that you will not push it. Certainly the sanitation of the canal will be cared for and there is no intention to let down on the character of the work now being performed.

JAMES R. MANN, M. C.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

CALIFORNIA: Los Angeles, December 7. Sec., Dr. Charles L. Tisdale, Butler Bldg., San Francisco.
DELAWARE: Regular, Dover, December 14; Homeopathic, Wilmington, December 14. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.
IOWA: State House, Des Moins, Dec. 7-9. Sec., Dr. L. A. Thomas.
KENTUCKY: The Armory, Louisville, December 14. Sec., Dr. J. N. McCormack, Bowling Green.
MARYLAND: 1211 Cathedral St., Baltimore, December 14-17. Sec., Dr. J. M. Scott, Hagerstown.
PENNSYLVANIA: Regular and Homeopathic, Philadelphia, December 14.17; Eclectic, Harrisburg, December 14-17. Secretary of the *Medical Council*, Nathan C. Schaeffer, Harrisburg.
VIRGINIA: Lynchburg, Dec. 14-17. Sec., Dr. R. S. Martin, Stuart.

The Medical School as a Part of the University

In the annual address in medicine at Yale University, Prof. W. H. Howell (*Science*, July 30, 1909, p. 129) points out the remarkable progress which *has been made* in medical education in this country within the last decade. He, however, calls attention to the fact that by far the greatest progress has been made in the teaching of the medical or biologic sciences. *The time of preparation* for the clinical years has been greatly lengthened and improved, while in the last two, or clinical, years the progress has been comparatively very slow; so slow in fact, that the methods and quality of instruction in these years, in the majority of American medical schools, is very little improved over that given to the former generation.

The explanation of this is probably to be sought in the fact that the clinical men are too often capable practitioners rather than scientific physicians. Too often they are so lacking in an adequate knowledge of laboratory methods and the medical sciences that one is inclined to ask what is the use of giving the student a scientific training if the man who instructs him in diagnosis and treatment neglects to show wherein this knowledge is applicable. Under present conditions so much time and energy are devoted to private practice by the clinical men that original investigation and scientific clinical instruction sadly suffer as a consequence.

As a remedy it is recommended that the clinical professors be paid the full salary of a full professor and be limited in their practice to the University Hospital. Howell thinks that America is at present in a good condition to try such an experiment as well as to carry out the recommendation of the Council on Medical Education of the American Medical Association, that there be added to the present regular course of instruction a year of hospital service as an obligatory part of the requirements for the degree in medicine or for the license to practice medicine.

North Dakota October Report

Dr. H. M. Wheeler, secretary of the North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, Oct. 5-7, 1909. The number of subjects examined in was 14; percentage required to pass, 75. The total number of candidates examined was 16, all of whom passed. Twelve reciprocal licenses were issued at this examination. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Bennett Medical College	(1908)	75
Northwestern University Medical School	(1909)	86
University of Iowa, Coll. of Med...(1907) 81;	(1909)	83

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SEMELINCIDENCE

To the Editor:—The suggestion of Dr. T. L. Hazzard (THE JOURNAL A. M. A., Nov. 13, 1909, liii, 1658; Sept. 18, 1909, liii, 963) to adopt the term "semelincident" to designate diseases that do not recur, is a good one. We think largely in words, and if this word with its significance is put clearly before the profession, something may be accomplished to explain practically certain phases of immunity.

As Dr. Hazzard intimates, the word is not entirely new, though apparently not in the dictionaries. My recollection is that I heard it as an undergraduate student, over twenty years ago. At any rate it was familiar to me at least as early as 1902, when it was used in a classification of infections and I have used it in a number of published articles.

The term "immunifacient" is also an excellent one, but of somewhat different meaning, as a number of diseases, such as diphtheria and influenza, are self-limiting, and immunize against themselves for a time. Whether there is an essential difference between the immunities thus produced or whether there is merely a difference in degree, is an important question.

Another interesting problem is with regard to a group of rare diseases of high mortality, such as cerebrospinal fever, equinia, tetanus, anthrax, etc. By the law of chance, a repetition of such a disease would be extremely rare but it is possible that large series might show statistically whether there is really a semelincidence.

A few diseases, like pneumonia, diphtheria and rheumatism, are said to predispose to recurrences but there seems to be some question as to the exact nature of the infection in the first and as to the infectiousness of the last while the predisposition in diphtheria is probably due to a chronic throat lesion.

Certain infections, such as tuberculosis, leprosy, syphilis and the malignant neoplasms, if these be due to micro-organisms, do not tend to spontaneous recovery so that immunization with germ products is not to be expected *a priori*, though one must always yield to the argument of fact. The old idea of "exhaustion of the soil" in the case of semelincident diseases is now commonly ridiculed but it must be admitted that in a crude, practical way, it represents a fact. Indeed, the expression is to be criticized rather from the agricultural than from the bacteriologic side. The modern theory of immunity may, with similar crudity, be interpreted as implying that the semelincident disease, instead of exhausting the soil, adds something to it, which prevents the further growth of a particular kind of germ, vegetable or animal as the case may be, without interfering either with normal physiologic processes or the growth of other germs. When we contemplate the fact that this process of addition or subtraction, may be repeated for half a dozen different diseases for the same individual without any apparent effect on his physiology, we are face to face with a very puzzling problem. *A priori*, "exhaustion of the soil" does not impress me as any more ridiculous than the opposite action and the exact nature of the alteration requires careful study, without reference to the popularity or authority of any hypothesis. A. L. BENEDICT, M.D., Buffalo.

The Public Service

Medical Department of the Army

Changes for the week ended Nov. 20, 1909:

Lyster, Theodore C., major, relieved from duty with the Isthmian Canal Commission, December 22; will proceed to the United States for orders.

Thornburgh, Robert M., capt., order for duty at Army General Hospital, San Francisco, revoked.

Wilson, James S., major, order for duty at Military Prison, Alcatraz Island, Cal., revoked; will proceed at the expiration of his present leave of absence to Fort Ethan Allen, Vt., for duty.

Kendall, William P., major, when relieved at Fort Ethan Allen, Vt., will proceed to Fort Riley, Kan., for duty.

Harris, Jesse R., capt., granted sick leave of absence for 3 months.

Hill, Eben C., 1st lieut., granted sick leave of absence for 21 days.

Lyster, William J. L., major, ordered from San Francisco, to Fort Oglethorpe, Ga., for duty.

Keefer, Frank R., major, granted leave of absence for 1 month, 7 days.

Ewing, Charles B., major, retired from active service, having been found disqualified for promotion.

Howard, Deane C., major, Ekwurzel, George M., capt., Keller, William L., capt., and Richardson, William H., 1st lieut., relieved from duty in Philippines Division; will sail February 15, for San Francisco.

Brown, Ira C., 1st lieut., M. R. C., ordered to proceed at the expiration of his present leave of absence to Fort Lawton, Wash., for duty.

Campbell, George F., 1st lieut., M. R. C., granted leave of absence for 3 months.

Jarrett, Arthur R., 1st lieut., M. R. C., granted leave of absence to December 29.

Norriss, Henry C. R., 1st lieut., M. R. C., ordered to active duty; will proceed to Vancouver Barracks, Wash., for duty.

Maguire, Daniel F., 1st lieut., M. R. C., ordered to active duty; will proceed to Fort Myer, Va., for duty.

Barney, Fred M., 1st lieut., M. R. C., relieved from duty at Fort Myer, Va., and ordered to Fort Clark, Tex., for duty.

Lamb, William R., 1st lieut., M. R. C., resignation accepted, to take effect November 18.

Eliot, Henry W., 1st lieut., M. R. C., relieved from further duty in the Philippines Division, and ordered to proceed at the expiration of his present leave of absence to Fort McKinley, Me., for duty.

Adair, George F., Kennedy, James S., Chase, Alpha M., and de Niedman, William F., 1st lieuts., M. R. C., relieved from duty in their present stations; will proceed February 5 from San Francisco, for Philippine service.

McCallum, Francis M., 1st lieut., M. R. C., relieved from duty at Schofield Barracks, H. T.; will proceed to San Francisco, on transport leaving Manila, P. I., February 15.

Mills, Robert H., dental surgeon, left Fort Riley, Kan., and returned to his proper station, Fort Adams, R. I.

Laflamme, Frank L. K., dental surgeon, arrived at Fort Benjamin Harrison, Ind., for duty.

Scott, Harold O., dental surgeon, ordered to Columbus Barracks, Ohio, for duty, at the expiration of his present leave of absence.

Rhoades, Rex. H., dental surgeon, relieved from duty at Columbus Barracks, Ohio, and ordered to San Francisco, in time to sail February 5 for Philippine service.

Ingalls, Raymond E., dental surgeon, relieved from duty in the Philippines Division, will sail February 15 for San Francisco.

Marshall, John S., E. and S. D. S., granted leave of absence for 3 months, when relieved from Philippine service.

Medical Corps of the Navy

Changes for the week ended Nov. 20, 1909:

Pickrell, G., surgeon, detached from duty in connection with fitting out the *Solace* and ordered to command that vessel when placed in service.

Streets, T. H., medical director, placed on the retired list from Nov. 20, 1909.

Blackwell, E. M., surgeon, detached from the Naval Academy and ordered to duty in connection with fitting out the *Solace*, and to duty on board that vessel when placed in service.

Holcomb, R. C., surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to duty in connection with fitting out the *Solace*, and to duty on board that vessel when placed in service.

Garton, W. M., surgeon, detailed from the *Ohio* and ordered to the Naval Hospital, Norfolk, Va.

Angeny, G. L., surgeon, ordered to the Naval Recruiting Station, Baltimore.

McDonnold, P. E., P. A. surgeon, detached from the Naval Academy and granted sick leave for 3 months.

Vickery, E. A., P. A. surgeon, detached from the Naval Hospital, Boston, and ordered to duty in connection with fitting out the *Solace*, and to duty on board that vessel when placed in service.

Schmidt, L. M., asst.-surgeon, detached from the Navy Yard, Charleston, S. C., and ordered to duty in connection with fitting out the *Solace*, and to duty on board that vessel when placed in service.

Clark, G. F., asst.-surgeon, detached from the Naval Recruiting Station, Baltimore, and ordered to duty in connection with fitting out the *Solace*, and to duty on board that vessel when placed in service.

Brister, J. M., P. A. surgeon, ordered to the Naval Academy.

Streets, T. H., medical director, detached from duty as a member of the Naval Retiring Board, Washington, D. C., and ordered home to wait orders.

Heiner, R. G., P. A. surgeon, detached from the *Albany* and ordered to the Navy Yard, Mare Island, Cal.

Public Health and Marine-Hospital Service

List of changes for the seven days ended Nov. 17, 1909:

Cobb, J. O., surgeon, granted 1 day's leave of absence, Nov. 11, 1909, on account of sickness.

Wertenbaker, C. P., surgeon, directed to report at the Bureau November 15, 1909, on special temporary duty.

Lavinder, C. H., P. A. surgeon, detailed to represent the Service at the meeting of the Chicago Medical Society, to be held in Chicago, Nov. 24, 1909.

Parker, H. B., P. A. surgeon, directed to report at the Bureau Nov. 19, 1909, on special temporary duty.

Corput, G. M., P. A. surgeon, granted 5 days' leave of absence from Nov. 12, 1909.

Fox, Carroll, P. A. surgeon, granted 10 days' leave of absence en route to station.

Goldberger, Joseph, P. A. surgeon, directed to proceed to Mexico City, Mex., on special temporary duty.

Lloyd, B. J., P. A. surgeon, granted 5 days leave of absence from Oct. 19, 1909.

Francis, Edward, P. A. surgeon, granted 2 days' leave of absence while en route to places mentioned in Department orders of Nov. 9, 1909.

Ebersole, R. E., P. A. surgeon, directed to report to the medical officer in command at San Francisco, for duty and assignment to quarters.

Bryan, Wm. M., asst.-surgeon, granted 30 days' leave of absence from Nov. 27, 1909.

Stiles, Ch. W., chief, Division of Zoology, Hygienic Laboratory, detailed to attend the meeting of the New Jersey Sanitary Association, to be held in Lakewood, N. J., Dec. 3-4, 1909.

Hunt, Reid, chief, Division of Pharmacology, Hygienic Laboratory, detailed to attend the meeting of the Council on Pharmacy and Chemistry of the American Medical Association, to be held in Chicago, Nov. 12-13, 1909.

Bailey, C. A., acting asst.-surgeon, directed to proceed to St. John N. B., on or about Nov. 23, 1909, for medical examination of aliens.

Cheney, E. L., acting asst.-surgeon, granted 21 days' leave of absence from Nov. 16, 1909.

Houghton, M. W., acting asst.-surgeon, granted 5 days' leave of absence from Nov. 18, 1909.

MacCaffry, W. B., acting asst.-surgeon, granted 2 days' leave of absence in October, 1909, under paragraph 210, Service Regulations.

Ransom, S. A., acting asst.-surgeon, granted 30 days' leave of absence from Nov. 11, 1909.

Rodman, J. C., acting asst.-surgeon, granted 5 days' leave of absence from Nov. 17, 1909.

Simonson, G. T., acting asst.-surgeon, granted 2 days' leave of absence from Nov. 16, 1909.

Brinckerhoff, W. R., asst. director, Leprosy Investigation Station, granted 30 days' leave of absence from Dec. 2, 1909.

Wilbert, Martin I., technical asst., Hygienic Laboratory, detailed to attend the meeting of the Council on Pharmacy and Chemistry of the American Medical Association, to be held in Chicago, Nov. 12-13, 1909.

BOARDS CONVENED

Board of medical officers convened to meet at the Marine Hospital, San Francisco, for the purpose of making a physical examination of two officers of the Revenue-Cutter Service. Detail for the board: Surgeon James M. Gassaway, chairman; Assistant Surgeon S. C. Hotchkiss, recorder.

Board of medical officers convened to meet at Astoria, Ore., for the purpose of making a physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Passed Assistant Surgeon J. M. Holt, chairman; Acting Assistant Surgeon Jay Tuttle, recorder.

Board of medical officers convened to meet at the Marine Hospital, Key West, Fla., for the purpose of making a physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon E. K. Sprague, chairman; Acting Assistant Surgeon S. D. W. Light, recorder.

Health Reports

The following have been reported to the Public Health Service, during the week ended Nov. 19, 1909:

SMALLPOX—UNITED STATES

California: Sacramento, Oct. 17-23, 1 case.
Georgia: Macon, Oct. 30-Nov. 6, 3 cases.
Illinois: Danville, Oct. 30-Nov. 6, 2 cases.
Kansas: Kansas City, Oct. 30-Nov. 6, 1 case.
Kentucky: Lexington, Oct. 24-30, 1 case.
Minnesota: Duluth, Oct. 30-Nov. 6, 1 case.
Mississippi: Holly Springs, Oct. 30-Nov. 6, 3 cases.
Montana: Butte, Oct. 15-21, 7 cases.
Tennessee: Memphis, Oct. 30-Nov. 6, 3 cases.
Texas: Eagle Pass, Oct. 24-30, 3 cases.
Washington: Bellingham, Oct. 24-30, 2 cases.
Wisconsin: La Crosse, Oct. 30-Nov. 6, 1 case; Milwaukee, 6 cases.

SMALLPOX—FOREIGN

[illegible] es, Aug. 1-31, 23 deaths.
[illegible] 27-Oct. 3, 1 death.
[illegible] 9-16, 2 cases.
[illegible] ase.
[illegible] ct. 3-9, 1 death.
[illegible], 58 cases; Naples, 9 cases, 1 death.
[illegible] 19-25, 1 case, in vicinity; Medellin, Oct. 31, 1 case; Orizaba, present; Puebla and present along the lines of railroad, present; Veracruz, Oct. 24-31, 2 cases, 3 deaths.
Persia: Meshed, Sept. 4, present.
Philippine Islands: Iloilo, July 1-Aug. 31, 237 cases, 142 deaths.
Russia: Warsaw, Sept. 12-18, 6 deaths.
Spain: Barcelona, Oct. 19-25, 1 death; Valencia, Oct. 17-23, 1 case; Vigo, present.
Turkey: Bagdad, Sept. 17-25, present; Constantinople, Oct. 18-24, present.

CHOLERA

China: Amoy, Sept. 26-Oct. 9, 65 deaths; Kulangsu, Sept. 26-Oct. 2, 3 deaths; Shanghai, present.
India: Bombay, Oct. 6-12, 3 deaths; Calcutta, Sept. 26-Oct. 2, 8 deaths; Negapatam, Sept. 11-17, 3 deaths.
Java: Batavia, Sept. 26-Oct. 2, 17 cases, 1 death.
Japan: Kyoto, to Oct. 26, 200 cases, 98 deaths; Moji, Oct. 16, 4 cases; Shinkoku (island), Matsuyama, Oct. 20, present; Wakamatsu, Oct. 16, present.
Korea: Epidemic along the Yalu River; Chemulpo, Sept. 28-Oct. 9, present; Pyeng Yang, present; Seoul, Sept. 19-28, 1,072 cases, 651 deaths.
Manchuria: Dalny, Oct. 3-9, 1 case.
Netherlands: Utrecht (province), Jaarsfeld, Oct. 20, 1 case, 1 death.
Philippine Islands: Manila, Sept. 12-Oct. 9, 73 cases, 58 deaths; Provinces, 1,004 cases, 741 deaths.
Russia, general, Oct. 3-10, 570 cases, 254 deaths; St. Petersburg, Oct. 17-22, 116 cases, 35 deaths.

YELLOW FEVER

Ecuador: Guayaquil, Oct. 1-15, 13 cases, 4 deaths.

PLAGUE

British East Africa: Kisumu, July 10-Aug. 24, 12 cases, 12 deaths.
Chile: Antofagasta, Oct. 16, present; Iquique, present; Mejillones, present.
China: Amoy, Sept. 26-Oct. 9, 71 deaths.
Ecuador: Guayaquil, Oct. 1-15, 16 deaths.
India, general, Sept. 26-Oct. 2, 4,377, cases, 3,460 deaths; Bengal, 48 cases, 31 deaths; Bombay, Sept. 22-28, 24 deaths, present; Calcutta, Sept. 26-Oct. 2, 11 deaths; Rangoon, 5 deaths.
Japan: Kobe, Oct. 3-16, 28 cases, 21 deaths, present; Shinkoku (island), Kochi, Oct. 20, present; Matsuyama, present.

Marriages

Emil Amberg, M.D., to Miss Cecile Siegel, both of Detroit, Mich., November 16.

Albert I. Civins, M.D., to Miss Bertha Zeupnyik, both of Cleveland, Ohio, October 19.

Arthur Edison Gammage, M.D., Chicago, to Miss Myra Gillis of Rio, Ill., November 4.

John J. C. Ross, M.D., to Miss Belle Ratcliffe, both of Bloomington, Ind., November 4.

Julius Arthur Toren, M.D., McCook, Neb., to Miss Ethel Ida Midgeley at Chicago, October 27.

Harry C. Weber, M.D., Louisville, Ky., to Miss Edna E. Hill of Memphis, Tenn., November 4.

Harry Stuckert, M.D., Doylestown, Pa., to Miss Lilian Radcliff of Philadelphia, November 10.

Wilfred Hueston, M.D., Nashwauk, Minn., to Miss Florence Weber of Milwaukee, Wis., recently.

Louis C. Lehr, M.D., Washington, D. C., to Miss Sallie Howard Conrad, at Baltimore, November 9.

Dayton C. Wiggin, M.R.C., U. S. Army, to Miss Marion V. Williamson of Washington, D. C., November 10.

Harold Blake Justice, M.D., Sapulpa, Okla., to Miss Shirley Louise Mouck of Morrison, Ill., November 7.

Frederick W. Shaw, M.D., Kansas City, Kan., to Miss Elizabeth Martin of National Military Home, Kan., November 10.

Deaths

James Wharton McLaughlin, M.D. Tulane University, New Orleans, 1867; a member of the American Medical Association; formerly president of the Southern Medical Association, State Medical Association of Texas, Austin District and Travis County medical societies, and the Texas Academy of Science; from 1897 to 1905, professor of medicine in the University of Texas, Galveston; and a member of the medical staff of the John Sealy Hospital; in 1907 appointed a member of the board of regents of the State University; a Confederate veteran; died at his home in Austin, November 13, aged 69.

George Seymour, M.D. New York University, New York City, 1865; a member of the Medical Society of the State of New York; for seven years a member of the Utica Board of Health; acting assistant surgeon in the army during the Civil War; a member of the staff of St. Elizabeth's, Faxton, and St. Luke's hospitals, Utica; one of the incorporators of the Utica Medical Library Association; died at his home, November 8, aged 70. The Utica Medical Library Association and the Oneida County Medical Society attended the funeral in a body.

John R. Moore, M.D. Chicago Medical College, 1873; a member of the American Medical Association; chief surgeon of the United States Steel Corporation's Lake Superior mines, local surgeon for the Chicago and Northwestern Railroad and a member of the surgical staff of the Ironwood, Mich., Hospital; was accidentally shot and seriously injured at his camp on Clark Lake, near Ironwood, November 7, and died at the Ironwood Hospital, November 13, as a result of his wounds, aged 59.

Charles Albert Palmer, M.D. Northwestern University Medical School, Chicago, 1876; a member of the American Medical Association; for seven years a member of the board of education of Princeton, Ill.; and for ten years a trustee of the township high school; twice mayor of Princeton; for a time president of the board of health; and a member of the local pension board; died at his home in Princeton, November 6, from pernicious anemia, aged 54.

John Jay Hardin Conner, M.D. University of Michigan, Ann Arbor, 1877; a member of the American Medical Association; surgeon of the Springside Coal Mining Company and Pana (Ill.) Coal Mining Company; secretary of the local pension board; formerly president of the District Medical Society of Central Illinois, and ex-secretary of the Pana Board of Health; died at his home November 10, from acute endocarditis, aged 60.

Morgan L. Bacon, M.D. Long Island College Hospital, Brooklyn, N. Y., 1872; a veteran of the Civil War; local surgeon of the Fall Brook Railroad Company; for thirteen years school director of Wellsboro, Pa.; a member of the local pension board, and health officer; died at his home in that place, November 2, aged 72.

Samuel Sherwell Carter, M.D. Long Island College Hospital, Brooklyn, N. Y., 1895; a member of the Medical Society of the State of New York; formerly a practitioner, and president of the board of health of Haverstraw, N. Y.; died suddenly in Bartlesville, Okla., where he was visiting, October 28.

Henry H. Setser, M.D. University of Louisville, Ky., 1875; formerly a member of the Indiana State Medical Association; president of the Leavenworth (Ind.) board of health, and formerly secretary of the Crawford county board of health; died at his home in Leavenworth, November 11, aged 57.

Henry Leander Bacon, M.D. Rush Medical College, Chicago, 1894; of New London, Wis.; a member of the State Medical Society of Wisconsin; a member of the local pension board, and school board; was accidentally shot and killed while deer-hunting near Rhinelander, November 8, aged 40.

Alexander R. Stephens, M.D. College of Physicians and Surgeons, Ont.; for fifty-seven years a practitioner of Collingwood, Ont.; formerly president of the Simcoe District Medical Society; died at his home Nov. 27, 1908, from senile debility, aged 84.

Hubert L. Gill, M.D. Southern Medical College, Atlanta, 1892; of Columbus, Ga.; formerly assistant to the chair of surgery in Atlanta Medical College; died suddenly at the home of his sister in Atlanta, Ga., November 11, from heart disease, aged 40.

Charles Kimball Cutter, M.D. Harvard Medical School, Boston, 1876; a member of the American Medical Association; died suddenly while prescribing for a patient in his office in Somerville, Mass., November 11, from valvular heart disease, aged 58.

William Adie Bell, M.D. College of Physicians and Surgeons, New York City, 1887; a member of the Medical Society of the State of New York; of Yonkers; died suddenly while making a professional call, November 15, from heart disease, aged 56.

Henry Martyn Northam, M.D. University of Michigan, Homeopathic College, Ann Arbor, 1893; formerly of New Middletown, Ohio; died at his home in Ann Arbor, Mich., October 31, from cerebral hemorrhage, aged 51.

Robert James Harvey, M.D. Kansas City, Mo., Medical College, 1900; Northwestern University Medical School, Chicago, 1901; of Aguilar, Colo.; died in Lamar, N. M., Aug. 10, 1908, from pulmonary tuberculosis, aged 29.

Delevan E. Blackman, M.D. University of Buffalo, N. Y., 1878; for several years a member of the attending staff of the Buffalo General Hospital; died at his home in that city, November 11, from bronchopneumonia.

Harriette C. Keatinge, M.D. New York Medical College and Hospital for Women, 1879; a pioneer woman practitioner of New Orleans; died at her home in New York City, November 11, from heart disease.

Silas Pinckney Owens, M.D. St. Louis College of Physicians and Surgeons, 1885; president of the pension board of Moberly, Mo.; died at his home in that city, November 2, from cerebral hemorrhage, aged 53.

Isaac R. Whitaker, M.D. Tulane University, New Orleans, 1858; commander of Whitaker's Scouts, C. S. A., during the Civil War; died at his home in Utica, Miss., November 6, from malarial fever, aged 75.

Samuel Thomas Howell, M.D. Jefferson Medical College, Philadelphia, 1871; a Confederate veteran; died at his home in Eden Park, Independence, Mo., July 4, from cancer of the stomach, aged 66.

Charles Carrow Thompson, M.D. Kentucky School of Medicine, Louisville, 1872; Baltimore Medical College, 1892; died at his home in Taylorville, Ill., November 4, from multiple neuritis, aged 60.

Byron B. Pettitt, M.D. American Eclectic Medical College, Cincinnati, 1893; of Oklahoma City, Okla.; died in Fort Worth, Texas, January 27, from burns received in a fire in a hotel, aged 56.

Allen Perry Johnston, M.D. Rush Medical College, Chicago, 1906; of Chicago; formerly an interne in the Chicago Policlinic Hospital; died in that institution, February 10, from pneumonia, aged 32.

Josephine Cunin, M.D. Bishops College, Montreal, 1895; L.R.C.P. and S., Edinburgh, 1895; formerly of Montreal; died at her home in St. Margaret's Bay, Jamaica, October 24, aged 48.

Albert M. Pherson, M.D. Miami Medical College, Cincinnati, 1876; a member of the American Medical Association; died at his home in Osborn, Ohio, October 7, from angina pectoris, aged 62.

Eden E. Rhodes, M.D. Medical College of Indiana, Indianapolis, 1886; a member of the Indiana State Medical Association; died at his home in Rochester, November 7, from pneumonia, aged 52.

George R. Hazlewood, M.D. Medical College of Indiana, Indianapolis, 1880; died at his home in English, Ind., November 10.

William Ferdinand Friedhofer, M.D. Cooper Medical College, San Francisco, 1893; died at his home in San Francisco, Nov. 29, 1908, from myocarditis and interstitial nephritis, aged 45.

Frank Edwin Card, M.D. University of Vermont, Burlington, 1889; formerly of North Adams, Mass.; died at his home in Providence, R. I., November 7, from pneumonia, aged 43.

Edward Allworth, M.D. Victoria College, Cobourg, Ont., 1861; one of the oldest practitioners of Essex county, Ont.; died at his home in Kingsville, November 9, aged 73.

Rolla C. Grant, M.D. New York Homeopathic Medical College, New York City, 1879; died at his home in Rochester, N. Y., November 8, from angina pectoris, aged 65.

James Davidson, M.D. University of Minnesota, Minneapolis, 1892; formerly of Duluth; died at his home in Salt Lake City, Utah, November 9, from asthma, aged 48.

William Van Bergen Ames (license, Ohio, 1896); for sixty-four years a practitioner; died at his home in Fremont, Ohio, November 6, from senile debility, aged 88.

Charles Edwin Hall, M.D. New York University, New York City, 1873; died at his home in Greenville, N. H., November 7, from cerebral hemorrhage, aged 61.

Otis Shields Sharp, M.D. Cincinnati College of Medicine and Surgery, 1884; died at his home in Dayton, Pa., October 21, from pneumonia, aged 49.

John Christofer Nahrung, M.D. Independent Medical College, Chicago, 1897; died at his home in Smithton, Mo., August 20, from nephritis, aged 79.

John T. Cox, M.D. Miami Medical College, Cincinnati, 1870; Confederate veteran; died at his home in Moberly, Mo., November 11, aged 70.

Theodore Koch, M.D. University of Berlin, Germany, 1852; died at his home in Baraboo, Wis., November 19, from heart disease, aged 81.

Addison Hawkins, M.D. Rush Medical College, Chicago, 1879; died at his home in Denver, Colo., November 8, from heart disease, aged 61.

George Morgan Clarke, M.D. Rush Medical College, Chicago, 1903; died at his home in Los Angeles, November 11, from pneumonia, aged 33.

Amy T. Mace, M.D. Harvey Medical College, Chicago, 1897; died at her home in Chicago, Oct. 15, 1908, from splenic leukemia, aged 59.

Z. Corwin Dixon (license, Ind., 1902); died at his home in Linton, Ind., November 10, from congestion of the liver, aged 54.

Nicholas G. Thomas, M.D. Washington University, Baltimore, 1868; died at his home in Apison, Tenn., November 8, aged 63.

Collins E. Ellis, M.D. University of Louisville, Ky., 1881; died at his home in Kansas City, Mo., November 7, aged 52.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The American Medical Association, Its Work and Its Enemies

The following is taken from the November issue of the *Ohio State Medical Journal*, from the department of "Medical Economics," edited by Dr. J. W. Clemmer:

"The Ohio delegation in the House of Delegates of the American Medical Association at the June session endorsed its policy and activities as published in the proceedings. The work of the nineteen committees, of the Board of Trustees, and of the executive department, as shown by their reports, carried on in the several branches affecting the interests of the profession, displayed untiring zeal and a business capacity unsurpassed by any other great corporation. The volume of business in organization work and in scientific attainments under the management of the House of Delegates requires and exhibits the tact and talent equal to those of any other national organization or a great railway system. Any one who will study the history of the Association in an impartial manner will find that the prosperity attending the present policy and management since 1902 is unequalled by any other great system or organization.

"Of the one hundred and fifty members of the House of Delegates, many of whom have given special and continuous attention to the interests of the Association, not one withheld his endorsement of the work of the Board of Trustees in its management of the business affairs."

"There is a reason for these endorsements. The property and publishing plant are managed in a manner to best meet the demands of a great and growing association. The Journal of the Association has no equal. The list of publications is constantly growing: The *Archives of Internal Medicine*, the National Directory, bi-monthly bulletins, a digest of new remedies, besides an increasing collection of data of interest to state boards, medical societies, colleges, legislative committees and the profession in general. The facilities have been amplified every few years. It was found necessary this year to increase the capacity of the publishing plant by a large appropriation for a new building.

"All this is in the happy contrast with non-progressive methods prior to the reorganization of the association. Membership has been doubled. The combined strength of component state associations is 67,362. The profession has been organized into an active, efficient body. It has learned its duties and its rights.

"Through the councils of the Association it has been safeguarded against the frauds and imposition of trades people. The profession has become a factor in matters of politics and sociology. Its influence is felt in state and national legislation. The medical interests of the people are made an essential factor in professional organization.

"The work of the national Association has been directed along many channels. Note the progress in medical education by improvements forced on medical colleges; note the public instruction on medical subjects by publication and a special lecturer; note the splendid work of the Council on Pharmacy and Chemistry, a work of far-reaching importance to both the profession and the laity; note the benefits that accrue to the efforts being directed to such subjects as patents and trade marks, regulation of membership in component societies, drug reform, defense of medical research, elaboration of ethical principles, etc.

"One of the most important labors conducted by the American Medical Association, that of national legislation for the public health defense, is altruistic, pure and simple, and under the leadership of our own Dr. Charles A. L. Reed. The character of this work is exampled by his activities and address before the National Association of State Food and Dairy Commissioners at its St. Louis meeting. He stood like a stone wall on the benzoate of soda question, in defense of our parent organization and the public, against the brazen coalition of manufacturing and political interests.

"In brief, all the officers and committees, bureaus and councils representing the government of the American Medical Association are accomplishing a stupendous work for the good of American medicine. The published transactions of the House of Delegates are convincing of the scientific worth and moral integrity of this work.

"The opposition of charlatans, healers and moneyed interests naturally attends the labor of the American Medical Association in the advancement of professional and public health interests." "It is to be expected that the American Medical Association will always have its enemies in and out of the profession. It is also expected that members of the organized profession will show their alliance and their allegiance to the parent organization. Members of other organizations are loyal to the principles and precepts of official regulation. Representation of component societies is provided to correct misrule. Any county society has an influence in the governing body of the American Medical Association. Each state association is represented by chosen delegates. These are the sources of our strength (or weakness) as a national organization. Progress or failure is compassed by the authority vested in state representation. Reformation of 'despotism' must issue from the same authority.

"Any one from the housetops of the profession may do much to create misunderstanding and confusion among the rank and file of a large membership. The question with the profession is whether it will give ear to such representation or trust its selected delegates. The component state associations should hold their delegates in the national body responsible for the government of that body. If definite results or changes are desired in the affairs of the American Medical Association the state association should so instruct its delegates. The recommendations for such changes would imply a careful study of the entire subject. Unbiased investigation, however rigid, can only result in good. Any suggestions for improvement of the national association which the present management or the House of Delegates may have overlooked, its members would gladly consider. On the other hand this body could not consider the grievances and complaints put in motion by any insurgents.

"The support of the American Medical Association by its large membership, if loyal to its best interests and continued progress, must adopt constructive and not destructive means. The national association will continue to be what representatives of component organizations make it and not what its enemies are striving to make it. Progress of American medicine as represented by the American Medical Association in the future as in the past, will be an index to its work. It needs no defense; it simply needs to be understood."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—First Weekly Meeting

GENERAL SUBJECT FOR THE MONTH: INFLAMMATIONS AND INFECTIONS OF THE UTERUS AND APPENDAGES

Anatomy

Uterus: Form, size, position, important relations. Ligaments, broad, round, uterosacral. Structure, cervix, body, serous, muscular and mucous coats. Attachments of vagina to cervix. Arteries and veins, nerves. Lymphatics.

Fallopian Tube: Position, portions, structure, blood supply. Broad ligament, structure, relations, contents.

Ovary: Shape, size, position, relations, ligaments. Structure, functions. Blood and nerve supply, lymphatics.

INFLAMMATIONS OF THE UTERUS

Acute Metritis

Classification of Metritis: (a) Etiological, parturition, trauma, bacteria, etc.; (b) pathological, catarrhal, suppurative, granular, ulcerative; (c) anatomical, endometritis, myometritis, parametritis, perimetritis.

Etiology of Acute Metritis: Predisposing causes, menstrual congestion and suppression, displacement, trauma, parturition, etc. Exciting causes, gonococcus, staphylococcus, streptococcus, etc. Secondary to vaginitis, etc.

Pathology: Gross changes in uterus, changes in mucous, muscular and peritoneal coats, in lymph channels and bloodvessels. Variations in intensity of infection, extension to surrounding structures.

Symptoms: Temperature, pain, painful urination and defecation, amenorrhea, leucorrhea, enlarged tender uterus, etc.

Treatment: Palliative, rest in bed, anodynes, douches. Expectant indications. Surgical indications and technic for curettage, for vaginal section.

REFERENCE BOOKS FOR THE MONTH

Dudley: Principles and Practice of Gynecology.
Ashton: Practice of Gynecology.
Montgomery: Practical Gynecology.
Reed: Text-book of Gynecology.
Webster: Diseases of Women.
American Text-book of Gynecology.

Society Proceedings

COMING MEETINGS

American Physiological Society, Washington, D. C., December 28-30.
Southern Surg. & Gynecological Assn., Hot Springs, Va., Dec. 20-21.

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirty-seventh Annual Meeting, held at Richmond, Va., Oct. 19-22, 1909

(Concluded from page 1762)

Teaching Hygiene in Elementary Schools

MISS ISABELLE F. HYAM, Dorchester, Mass.: The state has taken on itself the education of the children, and it seems reasonable that as much attention should be given to the child's body as to its mind. Children can rarely change their own environment, but in many ways they can control their lives in an effort at better living, if they are properly prepared. The school-house and school-room should be examples of cleanliness, and afford every means to help the child to live. It would seem hopeless to teach hygiene when the child has but to look about and see filth. The child is the center of his little world, and is most closely concerned with the home. The facts in the home are care of the home, furniture, food and its preparation, hygienic clothing and personal hygiene. The first lesson in ventilation is that there must be an outlet for the foul air at the top of the room, which can be illustrated and emphasized in a cardboard of block house. Scientific impersonation plays a large part in the education of the child. For some children who are physically unfit only the open-air school is proper. They learn to love the open air, and the benefits of such a school are obvious. Health is fundamental and in the school the child should be trained in habits of health. In order to accomplish this end conditions in the school-room must be wholesome. The school should be well-lighted and the air fresh. There should be time for play out of doors and facilities for bathing.

School Instruction in Hygiene and Sanitation

DR. JOHN W. RICHIE, Williamsburg, Va.: I shall refer only briefly to hygiene, limiting the scope of my remarks to the public school, between the fifth grade and the high school. The teaching of sanitation has proved a great success because it is made so simple that it can be taught to pupils below the high-school age. We force the pupil to examine everything and state the conclusions to be drawn from the evidence, and when the pupil accepts as facts what his own reason tells him is true, this is called the open-mindedness of youth. Much good can be done by teaching the facts as to a few specific diseases. Pupils need to be taught about the microscope, and plants and animals that grow in the body and cause disease. They need to be taught something of the defense of the body against germs in order that it may not seem a monstrous thing to put matter from a cow into the human body. They must be made to understand that food and fresh air are more important than "patent medicine." My experience has been that it is a perfectly simple matter to give the theoretical background to children, and he who would shorten the subject by omitting the simple remedy is in danger of breaking the circuit altogether. Everywhere we find intelligent people who believe in sanitation, but even among those people there is ignorance of the simplest principles of bacteriology. They seem to have no idea of what a real disease germ is, but burden themselves with useless precautions. For instance, they filter the water from the roof to free it of typhoid fever germs, overlooking entirely the closet in the back yard. The subject of sanitation should be allowed sufficient time to give pupils some understanding of the subject, and the pupils should be liberally supplied with printed matter for study. Bulletins should be sent to the teachers as well as to the pupils. This teaching has a decided effect in educating the parents as well as the children. The public drinking cup disappears quickly where sanitation is taught. The old hygiene was not practicable, but the new hygiene is practicable, and we should see to it that in teaching hygiene the conditions should be hygienic in the school-room.

The Way to Study Hygiene in the Normal Schools

DR. ADRIAN DE GARAY, Mexico City: The difficulty in this matter has always been as to the manner and form in which such knowledge is promulgated. It is necessary to give the best instruction to all the world, but above all in the primary schools. It is in a condition of health that the citizen becomes of value to the country. There should be two courses of hygiene, one general and the other special, each taught with thoroughness. We should try to make hygiene as well as other studies as practical and interesting as possible. Practical instruction can be given in three ways, the chemical and bacteriologic laboratories, by excursions and study in such places as theaters, water-supply houses, public buildings, etc., and by hygienic amusements. Hygiene should be one of the principal subjects taught in normal schools; it should be studied during the last part of the term; instruction should be given in an entirely practical and agreeable manner, laboratories established and hygienic trips organized.

Instruction in Personal and Public Hygiene in the Medical College

DR. F. F. WESBROOK, Minneapolis: Those in public health work are hard on the doctor, although we realize his difficulties, and we recognize that he has perhaps been the leading spirit in all the advances of hygiene. I am a teacher, and not a practitioner, yet I wish to pay my tribute of respect to the medical profession, which, through the American Medical Association, is doing its best to raise the standard of the profession by seeing that none may enter who are not well prepared. It is the desire to prepare the medical man to regulate matters, in conjunction with other forces with which he will come in contact, very much more than he has done in the past. While we do not expect to make them all medical hygienists, we do expect to prepare them to work with such forces as we have represented here.

Results of Federal Control of Viruses, Serums, Toxins and Analogous Products

DR. JOHN F. ANDERSON, Washington, D. C.: The results of Federal control have been: (1) Manufacturers have been required to put their barns, stables and laboratories into sanitary condition. (2) There has been complete separation of tetanus and tuberculosis work from the work of producing diphtheria antitoxin. (3) All establishments are required to be equipped with proper laboratory facilities. (4) Each lot of virus is required to be examined bacteriologically, and a special test made for tetanus bacilli, and detailed records kept of such examination. (5) The sale of the old style "dry" lymph points is no longer allowed. (6) All animals used for propagation of vaccine virus are required to be autopsied, and if the animal has been suffering from an incurable disease the virus is not allowed to be sold. (7) All serums are required to be examined where standards have been established for toxic contamination, and correctly labeled, and to state the date beyond which they cannot be expected to yield their specific effects, and to contain no excessive amount of preservatives. (8) Standards for diphtheria and tetanus antitoxins have been established.

How an Enlarged and Uniform National Health Administration May be Secured

DR. JOSEPH Y. PORTER, Key West, Fla.: The phantom of offended dignity has often arisen in the past to arouse suspicion of improper interference when the Federal government, through interstate commerce, has stopped to interpose authority, even in an advisory manner in the management of public health matters. This is true to-day, particularly in Massachusetts, Ohio and Illinois, in reference to sanitary matters, and the control of disease-producing conditions within their confines. By advocating an enlargement of the powers of the general government in health control throughout the country which shall be uniform and impartially administered in all sections of the country, it is not herein desired that the arguments advanced or the opinions expressed shall be understood as recommending or advising that the health police powers of a state shall be abridged or superseded by the general government, but rather that some of the difficulties in the present system of administration may be remedied and the awkwardness of many existing conditions corrected.

Tuberculosis from a Maritime Prophylactic Point of View

DR. ANTONIO MATIENZO, Mexico City: Having demonstrated that tuberculosis is a social danger, and that it finds at sea excellent conditions for the breeding of the germ which propogates it, I would propose that an office for medical inspection be established in the principal ports under the control of the sanitary authorities, fully authorized to examine every passenger, and to require steamship companies to establish in all their ships a special department with berths for tuberculous children. The infection of the air having been proved, this is all which should occupy the attention of the hygienist. All people should be prevented from expectorating on the floor and in the berths, and for all tuberculous passengers there should be placed some concise precepts in the room relating to the danger of expectoration to the patient himself as well as to every one else.

What May be Done to Improve the Hygiene of the City Dweller

DR. S. A. KNOPF, New York City: It is by thorough training of ourselves as physicists and sanitarians, the awakening of statesmen and philanthropists to their duties regarding public health and public welfare, the education of employer and employees, of the men and women of all classes of society, in general and personal education of the child at school and the practical application of the combined knowledge and experience gained in modern society, pedagogy and medicine that we may hope to make of the child of to-day the citizen of to-morrow, the ideal man or women, strong, healthy and vigorous, noble and even beautiful to behold. The general hygiene, which concerns all classes alike is that part for which federal, state or municipal health authorities, through their agents or officers, must be held responsible. There should be a more thorough method of cleansing glasses and spoons at soda fountains, and the placing of cuspidors where they can be used. The leather straps in the street cars should be replaced by celluloid straps. The average child should not be sent to school before eight or nine years of age and every city should have an abundance of outdoor playgrounds. Thousands of acres of roofs should be utilized for this purpose. Botanical excursions should be indulged in and respiratory exercises carried on. There is a great race suicide among the poor of New York City inasmuch as many of the children either die young or fill the schools in an undeveloped and unfit physical condition.

Prophylaxis in Exanthematic Typhus

DR. GENARO ESCALONA, Mexico: In the central table land of the Mexican Republic typhus assumes an endemic form; the mortality reaches a very high figure. The physicians of Mexico agree that Mexican typhus presents certain characteristics that are different from the European type. The disease does not have a sudden development. There is a period of ascension and descension through irregular manifestations. Three important points may be considered: (a) The sanitation of the town; (b) the disinfection of the premises occupied by the patient; (c) the disposal of articles coming in contact with the patient. The patient should be isolated and his bed-clothing disinfected by boiling or destroyed by fire. All toilet utensils should be well disinfected and the excreta should be carried off through the drain by an abundant amount of water. The skin should be bathed and the hair cut, as well as the mucous membrane disinfected.

Transmission of Syphilis by Vaccine

DR. FRANCISCO DE BERNALDEZ, Mexico City: The Jenner or arm-to-arm vaccination against smallpox has been discredited by almost all nations because of the possibility of syphilitic inoculation. We are now well aware that in order that this may take place it is necessary to have well-studied conditions, but much care must be used in collecting the lymph. From observations already made, it is stated that the lymph must be taken from persons over three years of age, that being the age at which hereditary syphilis makes itself apparent. The vaccine pustules must be of seven days' growth because the contagious infiltrations have a longer period of incubation. The transmission of syphilis through the agency of humanized vaccine can easily be avoided if we know the conditions under which such transmission is possible. The Jennerian vaccine is to be recommended because it confers a greater degree of and a more lasting immunity.

Report on Yellow Fever in the Mexican Republic from August 25, 1908, to Date

DR. EDOUARDO LICIAGA, Mexico City, Mexico. This is my sixteenth annual report as to the presence of yellow fever in Mexico. There are a number of isloated cases in different parts of the country. In Cuba native children are supposed to contract yellow fever in a mild form, and thus infect mosquitoes, thereby giving rise to isolated cases of yellow fever. The covering with oil of standing water, filling up holes, fumigation of dwelling houses and surveillance of railway passengers constitute some of the means at present employed in fighting this disease. In the ports of Coatzacoalcos, on the Gulf Coast, and Salina Cruz, on the Pacific, it is nearly four years since a single case of yellow fever has been observed.

Necessity of Isolating Syphilitic Prostitutes to Prevent the Propagation of the Disease

DR. JOAQUIN HUICI, Mexico City: The prophylaxis of syphilis is a serious and interesting question, and has given rise to a division among scientific men. This disease has caused more ravages in the human race than any other transmissible disease, not only rendering the individual useless for work, but endangering those with whom he comes in contact. A uniform set of regulations to control prostitutes should be adopted. Governments are under obligation to enact provisions tending to prevent the transmission of disease, and syphilis and gonorrhea being continually transmitted, should be included in that obligation, as public women are the principal sources of those diseases, and they are the ones to whom such provisions should be applied

Efficient Means of Checking Syphilitic and Gonorrheal Contamination

DR. JUAN BRENA, Zacatecas, Mexico: The efforts of an association like this would be fruitless without the cooperation of the social classes. In the effort for the extermination of leprosy and tuberculosis the people join spontaneously, but this is not true with reference to venereal disease. Fortunately, the conviction has grown as to the practical utility resulting from giving universal publicity to clear rules establishing the conditions which render immune communications between the healthy and venereal subjects. Pupils in schools are taught the evils resulting from the use of tobacco and alcohol, and it would be a meritorious work to instruct the older pupils regarding the deadly action of impure pleasures. Literature should be distributed explaining the gravity of these diseases, and the means of prevention. Municipal physicians and others appointed for the purpose should attend these patients free of charge and lectures on the subject should be provided for.

Scope of Public Hygiene in the Betterment of the Home Life in Towns and Cities

MR. ROBERT W. BRUERE, New York City: Every one seems to take it for granted not only that disease is curable, but that it is the business of the medical profession to cure it or to prevent it. It has been many years since the medical profession was regarded as a dispenser of medicine, and not as a preventer of disease, more particularly social disease. Last year there were 10,147 deaths from tuberculosis in New York, and about the same number the year before. The death-rate from other diseases has greatly decreased during the past seven years in New York, but this has not been the case with tuberculosis. Last year one association had charge of 4,000 infants, and everything was done that was possible by simple education and the teaching of hygiene to reduce mortality. The great difficulty encountered was that the mothers were not able to purchase the food that those children required; 10 per cent. of them were forced to earn wages away from home, and over 73 per cent. of the mothers belonged to families where the income was less than $15 a week. That is $300 or $400 less than the Committee on Standard of Living maintains is necessary for the average family. The medical profession has done much to teach the world that disease can be successfully prevented only when it is attacked by an organized community, but I believe that the death rate cannot be cut below 10 per cent. until the problem of the poverty of the worker is attacked.

Scope of Public Health in the Prevention of Dependency

MR. HOMER FOLKS, New York City: Public health work includes both the education of the individual and the community, and if the work could be carried on comprehensively, efficiently and adequately the number of dependents would be greatly reduced. Ill health is a prolific cause of poverty, whether due to individual or social causes. The first strong movement in New York for the prevention of tuberculosis was organized by a society concerned with the relief of the poor. Much remains to be done in the prevention of typhoid, while diphtheria, whooping-cough and scarlet fever are gradually being brought under control. We shall not make prominent headway against alcoholism until we have the support of public health authorities. The movement for the prevention of venereal diseases, from which the public-health authorities cannot much longer hold aloof, must ultimately result in a great lessening of the demand on our hospitals, institutions for children, institutions for the blind and insane asylums.

Sanitary Requirements of Ventilation

DR. W. A. EVANS, Chicago: Good air is the most important problem before health departments. Ten thousand deaths a year from bad meat, bad water or bad milk would produce a world-wide scandal, yet we accept 10,000 deaths from bad air with complacency. The following are the basic sanitary principles of ventilation: 1. Attention must be concentrated on the habitual zones of a room, meaning a space from 4 feet above the floor to 6½ feet above. 2. Dead zones and corner eddies must be encouraged as settling places for bacteria. Such spaces must be cleaned daily with moist methods. 3. The breathing zone must be occupied by an even-up current of air, moving at the rate of at least 60 feet a minute from multiple floor inlets to multiple floor outlets. The temperature of the air reaching the breathing zone should never be higher than 80° F. and is better if it is under 70°. 4. The ventilating air should never enter the room at more than 40 degrees below body temperature. 5. Air ducts must be short. 6. No particular attention should be paid to humidity. 7. The volume of air per quiet person per hour should be five hundred feet. 8. Under no circumstances should the windows be fixed, but a gale of wind should be allowed to blow through each twenty-four hours.

Ventilation of Industrial Establishments

DR. C. T. GRAHAM ROGERS, New York City: The Department of Labor of the State of New York has done much toward the betterment of public health in that state, besides which the Commissioner of Labor has sent a representative of the department to participate in this meeting. Some 430 separate air tests were made during six months of the fiscal year 1908, and a complete tabulation of the results may be found in the Eighth Annual Report of the Commissioner of Labor. Great strides have been made in improving the ventilation of schools and dwellings, but comparatively little progress has been made with the factories. It is to be hoped that some means will be secured to impress the laity with the importance of the subject. Inspections have been made of the New York bakeries, potteries, polishing and buffing rooms, tailor shops, cigar factories, clothing shops, jewelry stores, department stores and others. The cry in the past has been for more light, but now it is for more air. We need both, increasing the resistance of the body to disease, and making the nation stronger physically, mentally and morally.

Cooperative Efforts in Supervision and Control of Milk Supply

DR. F. D. BELL, New York City: The Board of Health of New York City requires a permit from every milk dealer in the city, and if the dealer does not conduct his business in accordance with the requirements he is brought into court. The average milk dealer knows little about the chemistry or bacteriology of milk, and an absolutely sterile milk is almost impossible to obtain because the public is not sufficiently educated to exact this quality of milk. The public is unwilling to pay for such a grade of milk, and the dealer and the average producer are not of a type capable of producing this quality. The average dairy farm is too small to produce milk economically and the dealers are unable to afford any systematic laboratory supervision, or proper buildings and apparatus which we have come to believe are necessary for the production of pure milk. Regulations have been promulgated with the health authorities which, if rigidly enforced, would mean that the towns would be without any milk supply at all. The dealer and health officer should consider themselves friends, and such a feeling can be brought about only by the gradual process of developing mutual confidence.

An Investigation of the Extent of the Bacterial Pollution of the Atmosphere by Mouth Spray

MR. C. E. A. WINSLOW, Brookline, Mass.: With the progress of exact knowledge sanitarians have been led to place less and less emphasis on the part played by the atmosphere in the spread of zymotic disease. It has been shown that quietly inspired air is germ free and most of the particles in the mouth spray are rather coarse and settle rapidly. It is not intended to minimize the real danger from mouth spray, as large numbers of bacilli are discharged in coughing by consumptive patients. Ziesche found in one case 20,000 tubercle bacilli on a glass plate of fifty square inches in area when exposed for half an hour from 16 to 32 inches in front of the mouth of a tuberculous patient. In workrooms, offices and such places the space between the heads of the workers should be at least three feet. This furnishes no basis for a belief that tuberculosis or any other disease is contracted to an appreciable extent through the inspired air, as the spray quickly settles and the conviction is not generally gaining ground that aërial infection of any sort is a minor factor in the spread of zymotic disease.

Sex Problems in Industrial Hygiene

MRS. FLORENCE KELLEY, New York City: It is more than one hundred years since the working people of England first began in the name of public health to get a shorter day for women. In 1847 a bill was passed in England limiting woman's labor to ten hours, but in 1895 in the enlightened state of Illinois, the Supreme Court held that it was unconstitutional to grant to women the same degree of protection. In the majority of our states it is lawful to require women to work in a factory or laundry or store any number of hours that a rush order may require. Our legal procedure is very curious. The Supreme Court is presumed to know only those items of common knowledge specifically laid before it, and it was necessary to collect some 162 pages of common knowledge. For some time there was a law in New York that girls should not work in the stores after 10 o'clock, but it was not enforced because of the claim that there were more important matters to look after. Failure to enforce this law proved in some cases just as fatal as strychnin. About twelve years ago the miners of Utah secured an eight-hour day because they worked underground, but the bakers of New York, who also work underground, failed in their efforts.

Relation of Life Insurance to Public Hygiene

Dr. Lee Frankel, Metropolitan Life Insurance Company: In no other country of the world would it be necessary to explain the relation of insurance to industrial and social hygiene. In Europe insurance is compulsory, and in the larger European cities the great mass of citizens are insured along the line of prevention. Our company distributed 4,000,000 pamphlets, entitled, "The War on Consumption," calling attention to the fact that there are places where the individual may obtain treatment. We desire to cooperate with any agency in the community toward the prevention of tuberculosis and other preventable diseases. In Chicago we were asked to distribute copies of the ballot, which enabled the people of that city to secure a municipal sanitarium. We are now making experiments of sending a nurse to every sick policy-holder, and have been successful so far. Our policy-holders are being visited weekly, and if desired this association may make use of our organization in the promotion of public health.

Scope and Value of the Daily Press and Press Bureaus

Dr. John A. Kingsbury, New York City: The scope of publicity in public health is as broad as the scope of publicity in politics, and in order to be effective it must be made as striking as it is possible to make it. It is our problem in public health to arouse slumbering humanity to a full realization of the meaning of the frightful fact that disease germs cause the death of over fifty per cent. of the human race, and that in addition to this suffering and poverty which can hardly be imagined, we must convince the public that this great sacrifice is almost wholly needless. It is only within the last few years that there has been any considerable demand for the knowledge given the world almost a quarter a century ago by Koch. We must learn from the "patent-medicine" man his secrets of publicity. The trouble so far is that all the money that has been given in this field of work has been put into the manufactory department and the advertising end of the business has been almost entirely neglected. We must get our goods into circulation. Moreover, there is a lack of proper cooperation between the producing and developing departments of our work. The American Public Health Association has long been in the business of producing knowledge of inestimable value. If advertisements can create new wants and new desires the satisfaction of which builds up business for others, surely practical publicity can create a demand for such knowledge, and the nature and scope of such work would be limited only by its ability to get results.

The Physiologic Aspects of Ventilation

Dr. Theodore Hough, University of Virginia: There is no argument against the hygienic importance of ventilation. The history of the subject shows that it is not so simple as is often supposed. The poisonous material in the air of the room does not come from the lungs but from the skin, clothing, decaying food particles in the mouth or catarrhal exudates, from the air passage. It is important to distinguish between the acute effects following exposure to vitiated air and those effects which are produced by prolonged exposure. The toxic material, so far as it is a factor, does harm chiefly when it acts over a comparatively long period, and we must seek elsewhere the explanation of the acute effect. While the introduction of fresh air is of great importance in removing the unfavorable physiological factors, it is even of more importance to maintain an even temperature of from 68 to 70° F., since at this temperature the humidity is almost negligible, while the other ill effects, especially on the nervous system, seem to be less noticeable and less important.

Age Problems in Industrial Hygiene

Dr. Owen R. Lovejoy, New York: In many states we are embarrassed by the attempt to secure the enactment, and after that the administration of laws regulating the ages at which children shall be employed, because of the fact that it is impossible to tell when the ages began. The relation of age to industrial employment needs no discussion, yet we constantly meet ignorant people who think that a child is a small man, and that burdens which are proper for the man are proper for the child, if measured according to the child's age. There is a period between 10 and 16 that is so revolutionary in its nature as scarcely to be exceeded by the needs of the infant. It may be safely predicted that the awakening to the dangers of typhoid and other diseases will in another decade make the health department one of the most important, if not the most important department in any of our city governments. It has been assumed that the best employment for the child is agricultural, but it has been shown recently that on many truck farms conditions prevail that are seriously detrimental to the child. Health officers should carefully study the relation of the industrial education of the community to the development of the physical life of the child.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Eighteenth Annual Meeting, held in Washington, D. C., Oct. 5-8, 1909

(Concluded from page 1769)

How to Keep War Ships Free from Infective Diseases

Surgeon R. C. Holcomb, U. S. N., showed first the prevalence of contagious diseases at the large training stations and outlined for discussion a method of keeping recruiting rendezvous free from infection. The recruit goes first to the receiving division, then to the observation division and finally to the clean division, from the latter of which the drafts are selected. He advocates barracks of the bungalow type, housing six men each, and constructed with a view to ease of disinfection. With this type of barracks less men are exposed when an outbreak of disease occurs and the work of disinfection is simple and relatively easy. The records of all epidemics on receiving ships are connected with overcrowding. The training station is an outgrowth of the old-time receiving ship.

Surgeon M. F. Gates, U. S. N., discussed the reception and care of recruits received on board ship. He believed that infections should be eliminated prior to the transfer of the men to ships, as receiving stations are sometimes foci of infection. Men should be inspected immediately on their arrival. Segregation is desirable. It is most important to have history of the recruits and a separate health record for the medical officer is desirable. He spoke of the value and needs of isolation wards, deck camps for isolation, camping parties for convalescents and then took up seriatim the consideration of the communicable diseases and the prevention of their spread. The essentials for the most ideal results are alertness of the medical officer and repeated inspection.

Surgeon C. M. Fiske had assigned to him the portion of the discussion referring to the care of the crew of a ship undergoing repairs in a navy yard. Medical officers must be familiar with local hygienic conditions as to climate, food and water supply, sewage, prevalence of infectious diseases, facilities of the station, etc., and must be prepared to make recommendations prior to arrival. The limitations of naval authority in the neighborhood must be taken into consideration. The conditions which attend the repairs of a ship in a navy yard are likely to be unhealthy; infectious diseases are usually introduced. The most efficient remedy lies in the unit barracks. Evil influences are the presence of civilian workmen and visitors on board, liberty parties, the food furnished by local contractors, the non-availability of sanitary systems on board, the proximity to shore, which favors the introduction of insects and vermin and the failure of civilian authorities to control contagious disease. They should be urged to report any indisposition however trivial. Daily exercise should be required. Workmen on board should be required to observe the regulations for the safeguarding of health. Separate toilets and other facilities should be provided for civilian employees. Fresh provisions should be carefully inspected. The laboratories of local hospitals should be utilized to detect bacilli carriers. There is need of a practicable system of drainage of a ship, when in dry dock.

Surgeon D. N. Carpenter, U. S. N., described the general and special measures for the care and protection of crews of ships in infected ports, including quarantine and sanitary recommendations, the duties of medical officers in infected ports, the sources of information regarding epidemics, the action to be taken in case infection occurs on board and the special measures to be taken in case of various national quarantinable, infectious and contagious, parasitic and venereal diseases.

The Public Health and Marine-Hospital Service

Surgeon Charles P. Wertenbaker, U. S. P. H. & M.-H. Service, in his paper on "The Duties of the Public Health and Marine Hospital Service," gave an exposition in general terms of the work done by the service and showed partially the points of contact between the spheres of the different services, thus indicating what the relations of the service might be to the medical departments of the army and navy.

Surgeon George B. Young, U. S. P. H. & M.-H. Service, discussed the possible relations between the Army, Navy and the Public Health and Marine-Hospital Service under the limitations of the existing law. There has never been any attempt to set forth briefly the legal status of the Public Health and Marine-Hospital Service to the other services as regards precedence, mutual support and possible interdependence in time of peace and war.

Medical Inspector L. W. Curtis, U. S. N., expressed his appreciation of the assistance rendered by the Public Health and Marine-Hospital Service during the recent cruise of the American battleship fleet. Advance information was frequently given in reference to the sanitary conditions in ports at which the fleet was about to call, and in other ways, the ship's surgeons had been materially assisted in keeping disease away from the fleet.

Lieut.-Col. G. C. Jones of the Canadian Medical Service stated that his long experience in public health work had led him to appreciate the value of the Public Health and Marine-Hospital Service, and that he had received most valuable information and assistance from the weekly reports issued by the service.

Laboratory Demonstrations

The association adjourned to the Public Health Laboratory, where the director, Passed Assistant Surgeon John F. Anderson, U. S. P. H. & M.-H. Service, described the scope work of the laboratory, and the chiefs of divisions demonstrated each his especial line of work. Afterward the members examined the laboratory and witnessed demonstrations of various kinds.

Entertainment

The entertainment provided for the members was lavish and varied. A reception was given in honor of the foreign delegates by Surgeon General Presley M. Rixey, U. S. N., president of the association, at his residence. Medical Director John C. Boyd, U. S. N., gave an informal buffet luncheon to members and foreign delegates at the New Willard. The members, foreign delegates and ladies were the guests of the president of the association and Mrs. Rixey at their summer residence, Netherfauld, Va. A mounted drill was given in the drill hall at Fort Myer through the courtesy of Col. Garrard. The Surgeon-General of the Army and Mrs. Torney gave a reception in honor of the association and its guests at the Shoreham. An automobile ride around Washington was arranged by the committee and participated in by the visiting ladies and many of the members and on the last afternoon the Surgeon-General of the Public Health and Marine-Hospital Service invited the members and guests to luncheon and an excursion to Mount Vernon on board the U. S. revenue cutter *Apache*. The women's entertainment committee held an informal reception for the visiting women at "The Highlands" and gave a luncheon for them at the New Willard Hotel.

Banquet

The official banquet in honor of the foreign visitors was given in the red room of the New Willard Hotel October 7. Covers were laid for 125. Surgeon-General Rixey, U. S. N., presided and Medical Director John C. Wise, U. S. N., officiated as toastmaster. The toast to the foreign countries represented by delegates was responded to by Sir Alfred Keogh, Royal Army Medical Corps, the senior foreign delegate, who expressed his appreciation of his cordial reception and of the hospitality of the association.

Advertisements

The executive committee decided to exclude all advertisements from the *Military Surgeon* excepting those approved by the American Medical Association. It also decided to increase the subscription price to $2.50 a year. Members hereafter will pay $3.50 per year, of which $2.50 will be applied as subscription and $1 as the annual dues.

Members Present

There were 172 who registered at the meeting. Of these 31 were representatives of the Army, 33 of the Navy, 12 of the Public Health and Marine-Hospital Service, 56 of the National Guard and Naval Reserve, 18 of the Medical Reserve Corps, 4 acting assistant surgeons, U. S. A., 3 officers of United States Volunteers and 1 Canadian officer.

MINNESOTA STATE MEDICAL ASSOCIATION

Forty-first Annual Meeting, held at Winona, Oct. 12-14, 1909

(Concluded from page 1768)

Right Inguinal Hernia and Concurrent Appendicitis

Dr. Walter Courtney, Brainerd: Observation of conditions found at the mouth of the hernial sac and the occasional necessity for post-herniotomy appendicectomies have led me, since 1904, to explore systematically and to remove diseased appendices through the internal ring when operating for the radical cure of right inguinal hernia. Since that time I have performed seventy-six appendicectomies in this manner. The result of this work has demonstrated the existence of concurrent appendicitis in a great majority of my cases of right inguinal hernia. As is well known, there is greater frequency of right over left inguinal hernias and the possibility of appendicitis as an etiologic factor should be considered. The operative technic offers no great difficulties in the majority of cases. The educated finger frequently can find and withdraw the appendix through the internal ring. Failing in this one or more narrow retractors may be inserted through the ring, permitting a view within the abdominal cavity; the cecum can thus be recognized by its blue or grayish color and withdrawn by rubber-tipped forceps. In only one case during the last two years did I find it necessary to go above the internal ring to explore and remove the appendix. No postoperative complications have followed this method of performing appendicectomies in my work.

DISCUSSION

Dr. Archibald McLaren, St. Paul: I think that in the past few years many surgical men have been led to the same truth, probably in the same way as Dr. Courtney. My first experience was much the same; I found a gangrenous appendix in the hernial sac. It is always a wise thing to remove the appendix under those conditions. I have had to make the cross-muscle incision oftener than Dr. Courtney has, and that is because I have not followed exactly his line. I find that one incision is much better than two separate ones, but if there is any difficulty in reaching the cecum that is the muscle incision that will least weaken the abdominal wall and if the surgeon cannot do the work properly through one incision there ought to be two.

Dr. A. T. Mann, Minneapolis: Two years ago I wrote a paper in which I mentioned the three classes in which we are liable to make a mistake. In one of the classes are the cases in which there are few symptoms, irregular, perhaps only a few symptoms of indigestion, an individual has more or less repeated attacks of indigestion that do not come from any known cause nor with any regularity that might point to any definite cause. In these cases, instead of making a diagnosis of chronic indigestion the physician should find out whether the appendix region is tender. If the patient complains of tenderness on this side then a definite examination of the appendix should be made, and if it is from the appendix the case is one of subacute exacerbation of chronic appendicitis, which may not have given further symptoms up to that point to call attention to the trouble, but which is liable to cause an acute attack and a bad attack and the appendix should be removed.

Dr. R. C. Dugan, Eyota: I have several times seen the appendix present in the hernial sac and now make a rule to obtain permission for its removal in all cases of right inguinal hernia. Such permission should be obtained in every case in which the abdomen is opened. In the future I shall follow Dr. Courtney's plan. I believe that the slight stretching of the internal ring, instead of being a menace to success, will rather be a benefit. Several times I have purposely cut the upper edge of the ring when the internal ring was round and indurated. I have had several patients complaining of sudden pain in the right side following a strain that simulated appendicitis very closely, but on passing the finger through the external ring a bulging at the inner ring could be felt. These patients are frequently cured by wearing a truss for a short time and are the only cases of hernia for which I ever prescribe a truss.

Cancers of the Cecum

Dr. W. J. Mayo, Rochester: Carcinoma of the cecum usually has its origin close to the ileocecal valve, therefore both the ascending colon and cecum are involved. The lymphatic drainage extends into the lymphatic glands at the base of the right colic artery and also into the ileocolic group. For all practical purposes malignant disease of the cecum and ascending colon can be considered as one. In estimating the feasibility of removing malignant diseases of the cecum examination of the liver for embolic carcinoma should not be forgotten. In our experience hepatic secondaries have been a larger cause of contraindication to radical operation in mechanically removable tumors than inoperable glandular metastasis. Rectal examination should be made for carcinomatous nodules in Douglas Pouch, the discovery of which would indicate an operable condition. The most important feature of surgery of the cecum is the question of obstruction. The mortality of necessary operations can be closely measured by the degree and acuteness of the condition. The late acute conditions should be treated by preliminary enterostomy. If immediate resection is made in obstruction the distended proximal gut should be emptied by Monk's tube. The most important technical feature in the operation for cancer of the cecum is the mobilization of the intestine for purposes of operation. The large intestine has a long mesentery. All its blood, nerve and lymph supply lies in the inner leaf of the mesentery and arises from the abdominal aorta and vena cava or in that vicinity. It is true that the outer leaf of the mesentery is exceedingly short if not absent in the ascending colon, but as the outer leaf contains no structures of importance it is only necessary to divide it, lift any part of the colon from its bed and swing it on its inner leaf to the midline. In separating the cecum and ascending colon and ligating the blood vessels identify the duodenum and ureter.

It will sometimes be found that a neighboring viscus has become involved and attached to the malignant growth. If conditions are otherwise favorable this should not be looked on as a contraindication to operation and multiple resections are made simultaneously.

The first steps in the resection of the cecum and ascending colon are: 1. Free incision through the right rectus muscle. 2. Liberation of the cecum and ascending colon by an incision through the outer peritoneal attachment. 3. With a piece of gauze the intestine with tumor and fat is wiped clean to the muscles as far as the superior mesenteric origin of the ileocolic and right colic vessels, which are tied at once enabling an accurate dissection of the mesenteric glands and fat. 4. Clamp hepatic flexure and lower ileum at proper points and remove the diseased segment. 5. Ligation of ends and sterilization. 6. Close the bowel ends with purse-string sutures. 7. Ileocolostomy, usually lateral anastomosis. 8. Closure of the mesenteric rent and the covering of the denuded surfaces with peritoneum.

DISCUSSION

Dr. Archibald McLaren, St. Paul: The way I have usually done is to start from the other side, but the next attempt I make shall be from the outside, because I am sure that is the practical way. In these tumors when it is necessary to make resection of the intestine my experience is that it is very unsatisfactory. I was amazed in looking over my own statistics to see how very unsatisfactory the results have been that I have obtained so far; 60 per cent of three-year cures is infinitely better than I have been able to get. Tuberculous growths are also of the same character and it is necessary to have a growth under the microscope before one can tell whether it is malignant or tuberculous in character.

SYMPOSIUM: COOPERATION OF STATE FORCES IN MINNESOTA MEDICINE

The State Board of Health

Dr. H. M. Bracken, Minneapolis: The opportunities for cooperation between organizations interested in public health matters is almost unlimited. The forces interested in public health are:

(1) State Departments:
- The Governor of the State.
- The State Board of Medical Examiners.
- The State Board of Health.
- The State Medical Society.
- The Department of Public Instruction.
- The Dairy and Food Department.
- The Labor Bureau.
- The Live Stock Sanitary Board.
- The State Board of Control.
- The State Drainage Commission.

(2) Schools and Institutions:
- Public Schools.
- Colleges.
- Normal Schools.
- The University.
- Medical Schools.
- State Institutions.

(3) The People:
- The Federation of Women's Clubs.
- The Commercial Clubs.
- The Labor Organizations.
- The Charities Organizations.
- The Municipal League.

Public health matters should be a common meeting ground for the above representative bodies and the State Sanitary Association affords the opportunity for such work. The Minnesota State Medical Association should take an interest in reaching the people through lecturers and through the county medical societies. Public health lecturers should be in the field; the tuberculosis exhibit should become a traveling exhibition rather than being specialized as now and necessary means should be obtained through the legislature for carrying on a campaign of education and meeting the necessities involved in the work. The Minnesota State Medical Association should take a deep interest in the work of the Minnesota State Board of Health, and someone should be kept at the capitol interested in legislative matters during each session of the legislature. Legislators are not well versed in matters pertaining to public health and it is easy for some selfish individual to kill a bill relating to medicine. The State University can do a great work by sending out students from the academic department with some knowledge of the principles involved in public health, while the special departments, such as medicine, law and engineering, should give their students some training in such matters.

The State Board of Medical Examiners

Dr. F. A. Knights, Minneapolis: All medical forces in the state ought to be influenced by the State Association because it is in position best to voice the sentiment and further the interest of the profession in the state. Much misunderstanding has existed as to the duties of the board. Many members of this society suppose it to be the function of the board to regulate illegal and irregular practice throughout the state and legally to prosecute the offenders. This is not the case, but, recognizing its moral obligations, also the demand of the profession, prosecutions have been brought which have almost uniformly been unsuccessful. For this the board has been severely criticised. Cooperation should be promoted and this effort would tend probably in the regulation of irregular practice. If Dr. McCormack were with us always he might educate the people for us and the rest would be easy. If Ramsey and Hennepin counties were sufficiently interested to assess their members from $3 to $5 each for three or four years and spend the money judiciously they could clean up the two cities. The rest of the state could be cleaned up if each member of this association would put up $1 for the same length of time. The services of an expert might be secured who should procure and collect evidence, put it in shape for use, give advice as to the best method of procedure by the county societies and spare the local men the annoyance of the thing so far as possible. This would require money, but it would be bread cast on the waters.

The State Board of Control

Dr. H. C. Tomlinson, St. Peter: I hesitate to speak of public institutions and their management, because in the eighteen years I have been a member of the Minnesota State Medical Association I do not recall ever having received a word of encouragement or any evidence of interest in the work of these institutions on the part of any member of the association. It may surprise you to know that under the State Board of Control there are over 6,000 people who require more or less constant medical supervision and that twenty-two medical men are engaged in this work. The difficulty is that when a patient is sent to one of these institutions he immediately departs from the physician's mind. This has its influence on the Board of Control. When we ask them for means to do medical work they say they have never heard a physician or medical body say anything about the necessity for such a demand. The general public is not responsible for this sort of ignorance, but it is the medical profession, you people sitting here. The State Board of Control is extremely anxious to do everything it can to help us, but it also recognizes the fact that we do not have the backing of the medical profession in any of the things we ask for. The idea seems to be that the sole function of these institutions consists in hiding certain people away from the public. We have on an average 375 operations in our institution in a year, and we have practically every form of disease, except acute contagious diseases, all the time. The members of our board are like the people from Missouri, they want to be "shown," and if the State Medical Association would cooperate with these institutions and with the authorities that control them, it would not only be an advantage to the medical profession, but to the public at large.

The University Medical School

Dr. Charles Lyman Greene, St. Paul: The position and standing of the school will serve as an index to the position and standing of the medical profession of the state. The advance of medical standards has made it possible for Minnesota to achieve the unique and desirable position of having but one fully organized medical school within her borders, and that school is of the state and for the state. The school is already ranked among the best in the United States. However, there are certain needs of the school, among others the maintenance of a great state hospital on the university campus; postgraduate instruction of a practical kind; a definite department of public health; a special fund for research and the employment of research workers, and the present close relation between public health and medical teaching must be maintained and extended. A better relation must also be established between the medical school and the individual physician and a way found to teach medicine in every hamlet in the state. Minnesota was a pioneer in establishing higher standards of medical education. Sectarian medicine is disappearing throughout the United States and it is fast becoming an impossibility for anyone to practice the healing art within the narrow limits of any so-called school. Another year will see the temporary hospital structure replaced by a modern building containing at least 100 beds, which will mark the beginning of the greater hospital of the future. We of the university teaching staff are enthusiastic and confident and with your help we shall build high for the present and yet higher for the future of Minnesota medicine.

The Medical Press

Dr. William A. Jones, Minneapolis: The old-time epigram, "Between the devil and the deep sea," might easily be transposed into the following sentence: "Vast numbers of the medical press after passing through the hands of the devil find an abiding place in the deep sea—a receptacle into which the doctor often throws his medical journal unopened and unread." Literally, this is not true. A large perecentage of the medical men religiously open and read their journals and claim that they are profited thereby; but, unfortunately, there are many medical men who find too little time to read or who are indifferent to current medical literature.

Dr. Jones then considered functions to be performed by the medical press. What it means to conduct, edit and publish a medical journal, its province and duty of its readers. Matter that should be contained in a medical journal. The Minnesota State Board of Medical Examiners, the Minnesota State Board of Health, the University Medical School and the Minnesota State Medical Society should unite as state forces in the education of the people on medical matters. A medical journal must be supported financially, and how. No journal with a limited subscription list that is published in a circumscribed community can ever be made a fortune-paying investment. The effort to maintain a journal that is clean and respectable should be supported by the physicians of the state.

The Lay Press

Mr. H. V. Jones, Editor Minneapolis Journal: The press represents a great responsibility in this country as does the medical fraternity. I think that if we had with us to-day a representative of the law we could say that these three great professions hold the greatest responsibilities of the people in their hands. Health, public opinion and justice are the foundation of our government and prosperity. I think that the medical men of the state and nation have been governed by their law too long. The people know too little of what they are doing. I do not understand the exact alliance you have with the state university medical department, but I am sure that there is a great work going on that the peoule should know about. I think the medical profession has been standing too long on ethics. It has a right to be heard and should speak out. I am not speaking in a personal sense, but the state association has a right to be heard. We have only to listen to papers we hear on occasions like this to catch the drift. Physicians would be surprised to learn how little people know of what is going on regarding the care of the health of the people. The newspaper men and the railroad man have always gotten along very well together, because the railroad man is generally ready to give results with real enthusiasm; but when we come to the doctor we find it difficult to make much progress, but I think if we could come together a little more we could soon reach an understanding. I am sure newspaper men would be glad to cooperate along the right lines with physician and official bodies. That work to my mind should be educational rather than in the line of news. The press has been too commercial, there has been a letting down of standards, and too much desire to make money at the expense of standard and principle, but I think a reaction has set in. I think the time has come for the medical association of this state to take up in some way a broad educational work, and I am sure it would have the hearty cooperation of the press in this state. I do not know just how a movement of this sort should be organized, but it occurs to me that the people should be told what physicians are doing and what they are going to do. I want to leave this thought with you, that the press of the state would be glad to cooperate in establishing a newspaper educational policy along the lines of what physicians are doing, omitting names, by studying the lines of work along which they are moving.

SYMPOSIUM: OPHTHALMIA NEONATORUM

Unnecessary Blindness

Dr. Frank C. Todd, Minneapolis: Ophthalmia neonatorum is a frequent cause of blindness. Statistics furnished by Dr. F. U. Davis and Dr. Dow show that 10 per cent. of the blind of all ages in the United States owe their blindness to this disease; from 10 to 11 per cent. of the blind in the school for the blind at Faribault are blind from this disease. While most severe cases result from gonococcus infection that others result from common pus infection. When the disease develops, it can only be properly treated by an ophthalmologist, assisted by trained nurses who should be in constant attendance. Two such nurses should be employed and preferably those skilled in the treatment of this particular disease. Patients whose parents are unable to employ nurses should be sent to a charity hospital. If midwives and physicians would always practice the prophylaxis discovered so long ago by Credé, the disease need not exist. The work of the Committee on Ophthalmia Neonatorum of the American Medical Association, headed by Dr. F. Park Lewis, should be endorsed, and the Minnesota State Medical Association should put itself on record in regard to details, as to the best way of eradicating this disease in Minnesota.

Etiology and Prophylaxis

Dr. J. C. Litzenburg, Minneapolis: The conjunctiva of the new-born infant is peculiarly liable to infection. Many germs may cause infection, but the gonococcus is responsible for at least 65 per cent of the cases and for nearly all the severe infections. Ophthalmia neonatorum may almost surely be prevented, and a 2 per cent. silver nitrate solution is the surest prophylactic, although the 1 per cent. silver nitrate is nearly as valuable. Bichlorid of mercury, 1 to 2,000, is a good substitute and should be used if one has not the silver. If a prophylactic were used in the eyes of every new-born baby the present rate of ophthalmia neonatorum will be greatly reduced. The treatment of the disease should always be entrusted to an ophthalmologist.

The Sterilization of Habitual Criminals and Degenerates

Dr. Burnside Foster, St. Paul: It will generally be admitted that a very large percentage of the habitual criminals, degenerates and sexual perverts in all communities are the offspring of parents of the same kind as themselves, and that their children will in all probability be tainted in like manner. There is then in every community a large class of individuals who are unfitted to marry and beget children. It may be broadly stated that no man or woman who is afflicted with either a communicable or an inheritable disease should marry or have sexual relations, whether married or not. How far the state can go in this matter is a difficult question to answer. The large class embraced under the comprehensive term, "degenerates," are sure to beget and procreate their kind, and this curse will be passed on to future generations unless radical means are taken to prevent it. While under present conditions the state cannot take charge of these degenerates in a community who have committed no crime, I believe it has the right to take those legally committed to its charge and under proper restriction so deal with them that they may no longer be a menace to society or to future generations. The state of Indiana has enacted a law by which an institution entrusted with the care of individuals of this class may, after consultation with a board of physicians appointed for that purpose, have performed an operation for the prevention of procreation. The operation is that of double vasectomy, and during the first year following the passage of this law 412 persons were operated on in the reformatory at Jeffersonville, Indiana, without a single accident or loss of an hour's time on the part of the prisoner.

The responsibility of the commission is a grave one in the way of distinguishing between hopeless cases and individuals who may recover, still I believe that this generation owes it to the next one to take every precaution to prevent the handing down of types of degeneracy. In Indiana sterilization has been applied, so far, only to the male, although the law permits of its application to women. Ligation and section of the Fallopian tubes would be as effectual in the female as vasectomy in the male, although a little more dangerous. Another much simpler method of sterilization may be available in the near future. I refer to the x-rays. By experiments on animals it has been shown that the development of the spermatozoa in the male and of the ovum in the female has been inhibited through the influence of the x-rays. It has been observed, however, that this sterilization usually has been temporary and that the animals regained their full power of reproduction later. X-ray operators have found that they themselves could produce no spermatozoa. Just what the x-ray does to the testes and ovaries is not known, and this method is uncertain and unscientific. This paper has been prepared for the purpose of suggesting that the Minnesota State Medical Association take definite steps to have this matter presented to the legislature with a view to having a law enacted in the State of Minnesota providing for a scientific method for the prevention of crime in future generations.

Empyema: Diagnosis and Treatment; A New Instrument for Securing Permanent Drainage

Dr. W. T. Adams, Elgin: It is the duty of physicians to have a better understanding of empyema, and more should be done to avoid the serious sequelæ so common after this disease. The disease is simple, and its treatment should be like that of any other accumulation of pus. It often follows pneumonia, and when elevated temperature continues after the normal limit in pneumonia, empyema is to be looked for. When fluid is diagnosed it should be differentiated with the exploring needle so that operation may be done early. In diagnosis the percussion note is valuable; if the note is flat there is fluid. Auscultation will sometimes be misleading on account of transmitted sounds, while the percussion note will be flat and is more to be relied on. Fever continuing after fluid is formed is certain to indicate infection. If pneumococcic, aspiration may cure, but if recovery is not very prompt, permanent drainage should be made very early. Early operations are preferable, before adhesions have had time to become very strong. Early operation should be made to stop autoinfection from the retained pus. All parts of the chest should be drained and walled off compartments may require separate drainage. Resection is not always essential and I advise against it. The chest should be drained without admitting air so as to force the lung to expand as the fluid is withdrawn. If the fluid is withdrawn without admitting air the lung will expand as the fluid runs out. The open method of operation does not invite expansion, but makes it impossible.

In order to drain the chest without admitting air, I have designed an instrument which meets the indications in the most perfect manner, and renders the early operation easy of accomplishment, and is cleanly and neat in every particular. The instrument is a modification of the cannula and trocar, so constructed that as the trocar is withdrawn from the cannula after its introduction in the chest, the proximal end of the cannula is closed against admitting air by pinching a piece of tubing. The cannula has a "T" branch with opening continuous with the tube of the cannula, which takes the fluid and delivers it into a sealed rubber bag which is deflated when attached, hence no air can enter the chest from that source. Another important feature of the instrument is a pneumatic cushion with which the shaft of the cannula is surrounded from a point on the distal side of a guard plate with which it is provided, to the distal end of the cannula, where it is inserted into a recess of the expanded end of the cannula, which makes it keep its place while the instrument is being pushed through the wall of the chest. When the instrument is properly applied, the pneumatic cushion extends through the wall of the chest with the cannula which it surrounds, and its middle portion is grasped by the chest wall, while the proximal end is without, and the distal end is within the chest. The cushion is double-walled, and the space between the walls, the ends of which are securely sealed, forms an air chamber to which is secured a small piece of rubber tubing, by means of which air is pumped into the interior of the cushion, which distends its outer walls, causing the two ends to balloon, which shapes the cushion like a dumbbell, the contracted center occupying the passage through the chest wall, while the ballooned ends serve to make an additional seal against admitting air, and forms soft, easy cushions to protect the body of the patient against the burden of the cannula.

SYMPOSIUM: TYPHOID FEVER, A MEDICAL AND ECONOMIC PROBLEM, AS ILLUSTRATED BY THE MANKATO EPIDEMIC OF 1908

The History of the Local Administrative Health Work

DR. A. O. BJELLAND, Mankato: The source of the water supply of Mankato is four deep artesian wells on Washington street. Two of these wells are within from 16 to 18 feet of the pumping station. The main outlet of the sewer also runs down Washington street, emptying into the river. A great flood occurred May 20-24. The gate in the main trunk of the sewer was left down on the night of June 24, 1908, presumably to keep the river from backing up into the sewers. This caused a backing up or a stasis of the sewage which backed up into a well pit of the new artesian well near the pumping station, hence sewage was pumped into the water system. Two of the other wells and suction mains were rusty and leaked and had not been properly looked after for a number of years. Then came a sudden sharp epidemic of diarrhea June 26; probably 2,000 people were affected. The people were at once advised to boil the city water so as to be on the safe side. The Minnesota State Board of Health was called on to make an investigation and June 29 Dr. Bracken, Dr. Hill and the health officer made an investigation of well pits and reservoirs and decided from the circumstantial evidence at this time, with the clinical evidence of intestinal disease, that the city water was contaminated and that we were in for an epidemic of diarrhea and predicted a possible typhoid epidemic. The Third street well was shut off, the reservoir cleaned and a flushing of the mains ordered. Samples of the city water from the taps and well pits were taken for analysis at the State Board of Health Laboratories, and on July 12 analysis showed colon bacilli present. July 11 and 12 Widals tests were made and these, together with clinical evidence, showed positively that the disease we had to deal with was typhoid fever. Over 100 Widal tests were made during the epidemic which showed positive reaction.

The first step taken by the health office, June 27, was to order the city water and milk boiled. The second step was to organize an emergency hospital of thirty-five beds. The German Catholic school was utilized for this purpose. A street cleaning and disinfecting department was organized and a general cleanup of the town instituted. The two daily city papers and a German paper were utilized to warn and instruct the people of Mankato how to handle and take care of themselves and how to avoid contracting typhoid fever. A wide-open systematic policy of publicity was inaugurated and was successful in holding down the epidemic in fifty-seven secondary cases. A health office was organized, a stenographer installed, maps of the water mains and sewer system were obtained from the engineer, a filing system was used so that as soon as the report of a case came in the health office, the health officer or assistant went to the house and wrote the history of the case. Visiting nurses were then sent to these places and by an object lesson in nursing, taught the family how to nurse the patient and how to avoid contracting the disease. The nurses made a house-to-house canvas, spreading the gospel of cleanliness and carefulness, and did a great work for us in general.

Having, in July, 1907, secured the passage of a milk ordinance, we were able to keep the typhoid infection from the milk. Through Mr. Manley, of the Minnesota State Food and Dairy Commission, this work was looked after under the direction of the health officer. A milk ordinance in any city making it necessary that all milk producers report promptly any contagious or infectious diseases existing in their families, is a great weapon in the hands of a health officer. Proprietors of all places where food or drink was sold were systematically warned to be careful and taught their responsibility as food and drink purveyors. The physicians in the city were urged to report all cases. Frequent consultations with Dr. Bracken, Professor Bass, consulting engineer, and the State Board of Health and Dr. Hill, the epidemiologist, together with a thorough inspection of the wells, sewers, water plant and the infected districts, gave us a thorough working knowledge of the situation and the needs thereof. The epidemic lasted from June 26 gradually and died out by Nov. 20, 1908. We had 464 cases reported into this office from July 7 to Nov. 20, 1908; 401 primary and 57 secondaries or contact cases, and six outside cases.

The Engineering History of the Mankato Typhoid Epidemic

PROF. F. H. BASS, Minneapolis: The widespread prevalence of typhoid caused suspicion to be directed toward the water supply, although it was known to come from below the surface of the ground at a depth of about 400 feet. An examination of the artesian wells revealed the fact that two of the four in use were defective. These wells terminated at the surface in pits which were approximately five feet in width and seven feet in depth. As the flow exceeded the demand, the wells furnishing water under pressure, were allowed to waste into the pits when not being drawn on. The overflow was in each case conducted from the pits to the sewer through pipes or orifices six inches in diameter. On June 26, an unusually high stage of water in the Minnesota river combined with a cloudburst backed the sewage up into the pump pits, whence it was drawn through the rusted out well pipes into the suction main and distributed thence to the city. One other combination of uncharted water and sewer and drainage pipes at the pumping station furnished a considerable amount to the pumps. The result of the investigation demonstrated the need of prompt remedial measures. A sanitary engineer was employed and has since remained in Mankato, reconstructing the public works of the city. The wells have been redrilled, newly piped and absolutely cut off from any possible connection with the sewerage system.

Diagnosis of Smallpox

DR. J. M. ARMSTRONG, St. Paul: Smallpox during the last few years has been an exceedingly mild disease, only six cases out of 978 being fatal, so that the mortality rate is 0.6 of 1 per cent., less perhaps than any other transmissible disease. Because of the benign type the disease has assumed, the diagnosis must often rest wholly on the objective lesions of the skin, which lesions present characters which make a positive diagnosis possible a few hours after their appearance. The papules appear first on the exposed parts, particularly the forehead and flexor surfaces of the wrists. They are under the epidermis, hard, round, flat-topped, umbilicated, rose-pink and waxy in appearance. All these characteristics are usually present. The entire evolution of the lesion from papule, vesicle, pustule, to scab formation, is regular and characteristic. The lesions vary in number, from a very few they may be so numerous as to become confluent, but the individual characteristics of the lesion are present in all cases. Vaccination is the only protection to the disease and if successfully performed, rarely fails to protect. Only 116 out of 978 patients ever claimed to have been vaccinated and many of these claims could not be substantiated.

KENTUCKY STATE MEDICAL ASSOCIATION

Fifty-fourth Annual Session, held at Louisville, Oct. 19-21, 1909

(Concluded from page 1682)

(Concluded from page 1682)

President's Address : Medical Organization and Work

DR. ISAAC A. SHIRLEY, Winchester: This large and representative gathering of Kentucky physicians is an undeniable endorsement of the organization movement inaugurated by the American Medical Association a few years ago. Before that time, with a membership of scarcely 300, we had an average of one-fifth that number in attendance at our annual gatherings. To-day there are more than 2,150 names enrolled on the society's books and we can count approximately one-third of that number here. Pleasing as this must be to every well wisher of legitimate medicine, there remains much work to be done. Without the fold there are more than 1,500 men and women who, to make our work effective and our joy complete, must be garnered in. To this end I propose to devote my best individual efforts, but realize that to accomplish the desired results will require work, constant work, on the part of every one. I ask your hearty and earnest cooperation.

An alarming defect in our law is the lack of punishment for criminal abortion. Judge Hines stated that in Kentucky there was no punishment for this crime prior to the period of quickening and after that it was only a high misdemeanor and at no time a felony, unless the mother died, and then only an every-day common murder.

I do not think that the work of the State Board of Health in ridding our state of quacks and other reforms accomplished has been properly appreciated. And while I do not agree with everything it has done, yet it has done so much more good than bad that the former largely outweighs the latter, and I personally thank them for it. I am in favor of a national reciprocity law; if a man is entitled to practice medicine in one state of the Union he should be entitled to practice in every other state, and I hope that such a law will soon be passed and that we shall do what we can to that end. I also want to enter my earnest protest against the almost universal habit of treating clergymen free of charge. I hope that this will not be considered an attack on the ministry, for the members of which I have the greatest respect, and many of whom are among my best friends; but I do not believe in discriminating in charity patients, or if any one objects to the word "charity," say poor patients. If a minister, on account of inadequate salary, too large a family, or any other reason, cannot pay for medical attention, then we should treat him willingly, gladly, gratis; but I have known many physicians who, on account of personal property, were kept guessing as to where the necessities of life were coming from, work for ministers whose salaries were sufficient to insure ease, comfort and luxury for nothing save "thank you," and sometimes not that. And this is what I object to and protest against.

Treatment of the Toxemia of Pregnancy

Dr. Edward Speidel, Louisville: Under favorable circumstances a multipara should be in charge of her physician from the sixth month, and a primipara from the third month of gestation. Even before that time the primipara may derive some relief in the period of nausea and vomiting, by intelligent directions of the attending physician, while at times he may detect early signs of and even ward off pernicious vomiting. Thereafter, the conduct of the case consists in careful regulation of the diet, especially in the last two months of gestation, proper advice in regard to exercise and clothing, avoidance of constipation, but most of all attention to the action of the kidneys. If the points recently brought out by Skeel in his excellent paper on the "Toxemia of Pregnancy" are confirmed by later investigations, then we will at least have something definite on which to base our therapy and the toxemias of pregnancy need no longer be treated in the haphazard empirical manner that has been the custom in the past. Again, if the two conditions, hyperemesis gravidarum and eclampsia present such pathologic findings, that they must be considered as early and late manifestations of the same process, then our treatment again narrows itself down to the elimination of the toxic agent that is common to them both. With the knowledge that the pregnant woman ordinarily has a blood-pressure not exceeding 150 mm., and that in toxemia it goes to 160 and 180 mm., and that under such circumstances there is a retinitis that is absolutely diagnostic of severe toxemia, then with such evidence we are justified in a resort to radical measures. An increase in blood-pressure above the normal 150 mm. with the retinal symptoms present in the early toxemia, will give us a basis for treatment and serve as a warning signal in the occasional patient who does not have albumin in the urine. Prompt elimination by all the emunctories and absolute restriction to a milk diet until marked improvement shows itself, should be the keynote of treatment. From 5 to 10 grains of calomel, followed by tablespoon-doses of Epsom salts, and then daily administration of small doses of Epsom salts is one of the simplest and best methods of combating autotoxemia and should begin the treatment. This with a milk diet alone, will often control the condition and the patient may go on safely to an uncomplicated delivery. When these measures alone are not effective, then the patient should be kept under careful observation and an account kept of the blood-pressure as indication for extreme measures. In the meantime, hot normal saline solution should be introduced into the colon, in quantities of a quart at a time, two or three times a day. Hot wet packs with the introduction of carefully wrapped and lighted electric bulbs in the pack to keep up the heat and produce a profuse sweating should also aid in elimination. Thyroid extract in doses of 5 grains every four hours, is advocated by those who consider the toxemia due to a functional insufficiency of the thyroid. Thyroid gland or extract administered in this way acts promptly in reducing blood-pressure, but its beneficial effects are counteracted by the fact that the drug causes a marked increase in tissue waste and therefore a considerable increase in the urea and other waste products in the blood and urine. It should be possible in most cases, if the above measures are carried out carefully and successfully, to carry the patient through a safe delivery, at any time, however, if there is a dangerous rise in blood-pressure, and if ocular symptoms present themselves, then the physician must understand that his patient is in extreme danger and that she may be liable to an eclamptic seizure at any time. There is then only the choice between venesection, the use of veratrum viride, and a premature delivery. With these pertinent objections to both venesection and veratrum viride it becomes evident that when the toxemia does not respond to the simple measures first advocated, that a premature delivery offers the best chance for the patient, according to modern ideas on this subject. In the multipara, this may mean a resort to bougies and slow manual dilatation; in the primipara with rigid undilatable cervix it will be best to resort to a preliminary manual stretching of the perineum and vagina, then vaginal Cesarean section and delivery.

Surgical Treatment of Cancer

Dr. A. J. Ochsner, Chicago, Ill.: 1. The earliest possible diagnosis of cancer must be made. 2. In case it is not possible to exclude cancer in the diagnosis, more competent counsel must be called. 3. The growth must be removed extensively even in the earliest cases. 4. In case the physician is not competent to make extensive removal of the growth, he should refer the case to one who will do this at once. 5. A search for new tests which will determine the presence of cancer early should be continued by scientific observers and supported by clinicians. 6. The search for the cause of cancer should be vigorously pushed. 7. At present, negative results in diagnosis by laboratory tests must not be considered of sufficient importance to prevent operative treatment when physical examination indicates the presence of cancer.

DISCUSSION

Dr. William J. Mayo, Rochester, Minn.: Dr. Ochsner, with his large clinical experience and keen observation, has placed his hand on the difficulty which has arisen in the past. That is, we as surgeons have asked medical men for a diagnosis of cancer which they could not make and then we have blamed them because the cases have been referred to us for operation at a period of time when it was impossible to do perhaps more than a palliative operation. We must have team work. It is impossible for the surgeon working alone, for the clinician working alone, or the experimental man working alone to say that his is the only way. It is by a combination of these that we can bring forward some method by which cancer in various parts of the body may be dealt with at an earlier time. The surgeon must have these patients early for operation if good results are to be obtained. And in order to do this he must have the cooperation of the internist, and it should be the duty of every practitioner of medicine to teach the people just as they do in Germany. In Germany to-day the reason better results are being attained than in this country is not because better work is being done, nor because the operations are more extensive in cases of cancer, but because there is a widespread effort on the part of the profession to teach the laity. This subject has been up before the American Medical Association and at present there is a committee on publication of information with reference to cancer. People must be taught some of the more common signs and symptoms of cancer. If we expect to accomplish more in the future than we have in the past the laboratory man, the clinician and the surgeon must work together in harmony.

Dr. William D. Haggard, Nashville, Tenn: Next to the great white plague, the subject of malignant disease in general is one that should receive our greatest interest because it is not generally appreciated that one out of eleven persons who have passed the age of 30 is going to die of some form of cancer. Out of 572 patients with cancer on whom Dr. Ochsner has operated in the last five years, approximately 100 of the lesions were of the breast, 100 of the uterus and 100 of the stomach. Therefore, it should be our earnest endeavor to concentrate our attention upon this subject. It would be well for us to remember the address of Dr. Maurice H. Richardson, as chairman of the Section on Surgery and Anatomy of the American Medical Association in 1905, in which he said that "every neoplasm, wherever situated, should be removed, if possible, at the earliest moment it is recognized." If we would simply take that lesson home with us we would make a great step in advance. It is said that 90 per cent. of all "lumps" in the breast in women over 30 will become malignant. If that is true it behooves all of us, when a woman complains of tumor of the breast, not to say that it is a glandular tumor or an adenofibroma, but to take it out. It is a small matter and microscopic examination will subsequently show whether or not it was malignant. And, if so, while the stitches are in place, a little incision can be made and the entire breast amputated in a classical way, and I venture to say that we will get 50 per cent. of cures in that type of case.

DR. J. GARLAND SHERRILL, Louisville: It is the duty of every physician to make it plain to his patients that cancer is not an incurable disease provided the remedy be applied early. There is one thing that the profession does not seem to be well aware of and that is cancer no longer appears after 40 to 60 years of age, but that it appears now as early as 12, 15 and 18 years. I have had recently under my care a girl 18 with cancer of the intestine extending from near the anus up to the left flexure of the colon. If we would impress on the profession that carcinoma exists in patients under 35 years of age we will have made a great step in advance at this meeting.

DR. WILLIAM H. WATHEN, Louisville: There is no one who appreciates the bad results that we have had in the surgical treatment of cancer more than he who has confined his work largely to uterine surgery and to intestinal surgery—structures that cannot be seen without a most thorough examination or without an exploration. Unfortunately most of the cases of uterine cancer that have been referred to me have been done so too late for more than a palliative operation. It is true that a few patients in whom the cancer had not involved the structures extensively, have remained permanently well. Whenever the cancer extends higher up and invades the parametrium, then it is a difficult matter to save these patients or to give them permanent relief; and permanent relief was not given until we were taught to operate by the suprapubic method and to enucleate the cancerous tissues far down on each side, removing the diseased parametria and, if necessary, dissecting the ureter. Some of these patients when so operated on have remained permanently well. I have one patient in whom there was an extensive involvement of the structures, who has remained well for three or four years, while I have had others in which the relief was of shorter duration. Permanent results would be much better if we saw these patients with cancer of the uterus earlier.

DR. A. J. OCHSNER, Chicago: In regard to the education of the public with reference to cancer, there is one thing which is very difficult to overcome, namely, almost every person in every town in this country knows of her friends who have had cancer and who have undergone operations and perhaps have died from the return of the disease. But very few of these people know of any patients who have recovered permanently, because those who recover permanently from this disease do not want their friends to know they had cancer and had undergone operation for its removal. I meet this condition constantly.

Prophylaxis in Medicine

DR. C. G. STEPHENSON, Becknersville: Our duty is to prevent or to remove all injurious external conditions which experience has shown will contribute to the development of disease and to strengthen or improve the faulty constitution and thus remove predisposition to disease. General prophylaxis consists in the employment of measures against conditions which are injurious to and will produce disease in individuals belonging to the same group. Prophylaxis should be provided for by the nation, state, county and city, and this being the case our national and state boards need to be quickened to a fuller realization of the service they owe to the individuals of this nation. They should endeavor to make the people of the United States a strong people, a happy people and a more useful people; a people whose bodies shall possess such physical resistance to disease as to make them immune to the many diseases that bear on people under ordinary conditions of life. A campaign of health education is being constantly waged, but it should receive a new impetus. This new impetus would be given by the establishment of a health bureau at Washington as a foundation source from which to draw that which would contribute to making people happier, stronger and more useful. Individual prophylaxis belongs directly to the realm of the family physician. One encouraging feature in modern civilization is the general interest which is being aroused in the matter of prevention of disease and death. Organizations composed of both lay and professional men are on the increase, educating people to a realization of the duty they owe to themselves and their neighbors. The demand for, and securing of, pure food and drug laws are some of the fruits of the organized effort that is being made. All advances have been the result of agitation and education among the laity by physicians.

Treatment of Chronic Amebic Dysentery

DR. GRANVILLE S. HANES, Louisville: My remarks relate chiefly to my own experience in the management of chronic amebic dysentery in our own climate. First, the patient is put to bed in a properly appointed room for the sick. He is not required to remain constantly in bed, but rest in the recumbent posture is the attitude that he should occupy chiefly. Second, it is almost a universal practice to make the administration of a purgative the first step in the treatment of these patients. I seldom resort to such a measure. It is my opinion that the nausea, exhaustion and general disturbance to the digestion that such a procedure precipitates is not justified by the results obtained. Third, many patients affected with chronic amebic dysentery are very much emaciated. I have found that this condition is almost always due to an insufficient amount of food. It has long been customary to restrict the patient's diet to a poorly nutritious food in any form of diarrhea. Fourth, it is absolutely inhuman to withhold opium when patients can be so promptly and completely relieved by its use. The relief from the terrible pain, straining and general exhaustion is beneficial to the patient and more than counteracts the ill effect the drug produces. It is much better to give opium when necessary and overcome its constipating effects by small doses of salts or other purgatives. Fifth, internal medication is considered by many to be the most important feature in the treatment of amebic dysentery. The solutions employed in irrigating the large gut for amebic infection are too numerous to mention. Quinin, copper sulphate, silver nitrate, tannic acid and permanganate of potassium are those most frequently employed. They all have the objection of acting as irritants to the mucous membrane when used in sufficient strength to kill and arrest the development of the ameba. For more than a year, I have been using ordinary commercial coal oil for this purpose. Its use was suggested to me on account of its deadly influence on parasites found on domestic animals. The crude petroleum also being used to prevent the development of mosquitoes. After experimenting with it for some time I was surprised to find that it was not irritating to the mucous membrane nor was it absorbed when retained in the gut for twenty-four hours, or even longer. Instead of its effect being that of an irritant it is bland and acts as a sedative to the mucous surface. It will not only remain in the bowel for a long period, but the gut will tolerate larger quantities than it will of water or aqueous solutions of any kind.

I have treated 36 cases of amebic dysentery in the past eighteen months. At one time I entertained the belief that a real amebic infection could never be looked on as being absolutely free from recurring attacks. I have abandoned this belief, and it is now my opinion that many patients are cured in whom the diagnosis was never known. If the infection is superficial and situated low in the gut and is of a very mild type it will yield to treatment with but little difficulty. If, on the contrary, the infection is severe and the disease is extensive in the upper limits of the large gut, the cure is exceedingly difficult, and, so far as we know, it may never be made permanent. In the entire number of patients treated, there was not one who did not show the infection in the rectum and signoid. While it is said that the cecum, hepatic and splenic flexures are the most frequent sites of disease, I cannot believe that this is true. If there is infection higher up in the gut it seems reasonable that the sigmoid and rectum would also become infected when they are the receptacles that constantly retain the drainage from all diseased surfaces above.

Clinical Diagnosis of Amebic Dysentery

Dr. Carl D. Render, Louisville: This is essentially the detention of motile amebas that have been obtained from the intestinal tract. It is usually taught that the stools should be examined for these protozoa. It has been shown repeatedly that this method requires a great deal more time and is much less reliable than that of obtaining the specimen directly from the surface of the ulcer. I never rely on the examination of the stools except in cases in which there is no lesion that may be detected in the rectum or sigmoid. In almost every case of chronic amebic dysentery ulcers are present in the rectum and sigmoid. After one has seen and treated a number of these cases it is with but little difficulty that a diagnosis can be made reasonably certain from the patient's general appearance and the history obtained from him. Motile amebas are sought only to confirm the probable diagnosis. The technic employed in exposing the ulcer and obtaining the specimen requires special attention. Unless the specimen is kept at the proper temperature and spread on the slide in the correct way, failure to detect the amebas will likely result.

Dangers of Animal Tuberculosis to the Public Health

Dr. F. T. Eisenman, Louisville: The unsuspected tuberculous cow is a very serious menace to the public health, and her true condition is seldom known until the tuberculin test is applied. It is then we often find that cows considered to be in the best of health and living under the most sanitary conditions react to the extent of from 5 to 60 per cent. Recently a herd consisting of 90 cows, when tested with tuberculin was found to contain 54 diseased cows and 8 suspicious ones. On Dec. 15, 1908, the Jefferson County Fiscal Court, anxious to determine accurately to what extent milk coming into Louisville was infected with tuberculosis, appropriated $1,200 for the purpose of carrying on the test by guinea-pig inoculation. The partial report of this investigation disclosed the fact that of 119 samples of milk taken from fifty-three dairies of various counties, 39.1 per cent. were proved to be tuberculous. The announcement of this result caused considerable alarm, but as the test was conducted by Dr. Cyrus W. Field, pathologist and bacteriologist of the University of Louisville, an eminent authority on the subject, the accuracy of the test was never doubted. When the attention of the State Board of Health was called to the dangerous character of Louisville's milk supply, a proclamation was issued making it compulsory for all cows in the state to show negative reaction to tuberculin before the milk could be sold. A little over three years ago, the Jefferson County Medical Society, realizing the need of milk on the purity of which the members could depend, appointed a milk commission and it is now possible to obtain a certified milk which meets all the requirements of the society. A low bacterial content is required and freedom from pathogenic organisms. This makes it necessary that every cow shall be tested before entering a certified herd, and once a year thereafter. Dairymen producing certified milk have killed over forty cows that they have purchased for additions to their herds and which have reacted to the test. These dairymen are experienced and felt that they could without fail select cows free from disease. Recently, samples of the certified milk were injected in a large number of guinea-pigs and not one showed tuberculous infection.

In Louisville, of the large number of general hospitals and infirmaries, one only uses milk from tested herds and undoubtedly many patients are infected from tuberculous milk. Millions of dollars are being spent for the cure of tuberculosis and yet the positively known greatest source of human tuberculosis, the tuberculous dairy cow, is being continually ignored and people are constantly being infected, that many more millions of dollars may be spent in their attempted cure. The time is coming when the public will demand of the profession and the health authorities the suppression of tuberculous milk. It is to be hoped that this time will soon come and that prior to it, all the members of the profession, including the health authorities, will be awakened to their responsibilities in the matter.

Diagnosis of Incipient Tuberculosis

Dr. O. W. Rash, Owensboro: The diagnosis of incipient tuberculosis is not difficult to the physician who realizes the prevalence of the disease, who observes the temperature of his patients, who makes a thorough examination of the chest in all suspicious cases, and who uses the tuberculin test with care.

What More Can Our Profession Do To Decrease the Spread of Tuberculosis?

Dr. Jacob Glahn, Owensboro: There are recorded between 6,000 and 7,000 deaths in the State of Kentucky alone during one year, and if we multiply this by five, we have over 30,000 persons ill with tuberculosis at this time, and there is no telling how many more obscure cases exist. This great loss of life, due to tuberculosis, is monstrous and abhorrent, and should not be, for more people die of tuberculosis than the fiercest war has yet destroyed in the same length of time; but in the prosecution of a war, special sums of money are levied to meet the expenses, and for the white plague, which destroys our fellow beings in such an insidious manner, nothing is done by our legislative bodies. Therefore, if the brotherhood of man cannot assert itself spontaneously, and come to the succor of the ill brothers, then the state governments should and must arouse themselves and allow a sufficiency of money under the control of the state boards of health and the various antituberculosis leagues, and municipalities, to establish and carry on simple and ample tuberculosis sanatoria in every county in the state. Every life saved will become a fixed asset, and a useful citizen will be preserved to the state.

Diagnosis and Treatment of General Peritonitis

Dr. John R. Wathen, Louisville: The diagnosis and the differential diagnosis of peritonitis as in many other surgical diseases of the abdomen, are often best made by an early exploratory incision; and much valuable time has been lost waiting for a well-developed case of diffuse suppurative peritonitis before a conclusion was reached, when timely operation would have cured the case, but which later has become almost hopeless. The basic principle in the modern treatment is the prevention or the retardation of absorption of septic material. This is accomplished first, and most important, by the Fowler position before and after the operation and even until convalescence is well advanced, and, secondly, by opening the abdomen to relieve the tension, which so greatly favors this absorption. Ochsner has called attention to the avoidance of food or drink by the stomach, and the application of cold to the abdomen, thus preventing peristalsis and in this way lessening the diffusion of the infective material over the peritoneal surface. All are agreed that rapid operation with a closure of the point or points of leakage is the thing most desired. This closure should be accomplished by the simplest, most rapid and safest method and provided with abundant drainage, for fear of an imperfect stoppage of the leak. This drainage should consist preferably of fenestrated soft rubber tubes and loose gauze packings. It seems now to be the consensus of opinion of the most successful operators that the less we manipulate, wash out or handle the intestines, the better are the patient's chances for recovery. The post-operative treatment consists of introducing continuously saline solution by rectum—protoclysis or enteroclysis. Murphy asserts that it is seldom correctly given, and describes this method practically as follows: The fluid should be administered through a fountain syringe to which is attached a hard rubber or glass vaginal douche tip with multiple openings. The tube should be flexed almost to right angles three inches from its tip. A straight tube should not be used, as the tip produces pressure on the posterior wall of the rectum when the patient is in the Fowler position. The tube is inserted in the rectum to the flexion angle and secured in place by adhesive strips, binding it to the side of the thigh so that it cannot come out; the rubber tubing is placed under the bedding to the head or foot of the bed, to which the fountain is attached. It should be suspended from 6 to 14 inches above the level of the buttocks and raised or lowered to just overbalance hydrostatically the intra-abdominal pressure; *i. e.*, it must be just high enough to require from forty to sixty minutes for one and one-half pints to flow in, the usual quantity given every two hours. The flow must be controlled by gravity alone, and never by a forceps or constriction on the tube, so that when the patient endeavors to void flatus or strain, the fluid can rapidly flow back into the can, otherwise it will be discharged in the bed. It is this ease of flow to and from the bowel that insures against over-distention and expulsion on the linen. The fountain had better be a glass or graded can, so that the flow can be estimated. The temperature of the water in the syringe can be maintained at 100 degrees by encasement in hot water bags. The syringe is refilled every two hours. The tube should not be removed from the rectum for two or three days. When the nurse complains that the solution is not being retained, it is certain that it is not being properly given; even children tolerate proctoclysis surprisingly well.

Treatment of Compound Fractures

DR. J. G. CARPENTER, Stanford: Shock must first be treated and the physicomental state of the patient considered. Then the flesh wound, bone wound and the field of the wound should be thoroughly cleansed and hemorrhage arrested. The wound being asepticized, I reduce the fracture, with or without drainage, as the case may demand. There should be complete coaptation of the fractured ends with immobilization of the fracture; if necessary, with bone rings, bone pegs, silver wire or chromicized catgut ligatures. In compound comminuted fractures, the fragments should be fastened together or to the shaft. We should remove the detached fragments of bone, cleanse and place them in a 1/1000 or 1/2000 bichlorid of mercury solution, then in a warm saline solution at the temperature of the blood, and transplant them into the wound. We should resort to drainage, if necessary, and apply an antiseptic dressing. The fractured bone should be immobilized at the proximal and distal points, with proper springs and extension and counter-extension, with complete rest of the limb.

Management of Burns

DR. C. C. GARR, Lexington: There are two general classifications of burns: First, in regard to depth—first, second and third degree. Second, in regard to cause—(1) flame; (2) hot or molten metal; (3) steam; (4) electricity; (5) chemical; (6) *x*-ray. Constitutional treatment is, at first, most important. It is very essential to relieve pain and combat shock. In doing this morphin, atropin, adrenalin chlorid and proctoclysis are serviceable. For the local treatment, I prefer the old-time carron oil as it relieves the pain and hastens, but does not increase, sloughing. Picric acid and other applications may be used. After the granulations are healthy the only rational thing is skin-grafting. I use a modified Thiersch graft, employing an air dressing.

The Social Evil

One evening was devoted to a discussion of the social evil. Dr. C. H. Vaught, Richmond, discussed the cost of venereal peril from the standpoint of the general practitioner; Hon. R. W. Bingham, Louisville, discussed it from the viewpoint of the lawyer; Rev. E. L. Powell, Louisville, from the standpoint of the minister, and Mr. J. H. Hager, Louisville, from the standpoint of a superintendent of police. A general discussion followed.

Book Notices

ETUDES ANATOMO-CLINIQUES: COEUR—VAISSEAUX—POUMONS. Par le Dr. Raymond Tripier, Professeur à la Faculté de Médecine de Lyon. Paper. Pp. 604, with illustrations. Price, 10 francs. Paris: G. Steinheil, 1909.

The author endeavors to explain the phenomena and causation of the diseases which he considers, by the anatomic conditions which develop and characterize them. The subjects which he discusses are endocarditis, syphilitic aortitis, atheroma of the mitral valves, arteriosclerosis, the rôle of the circulation of the blood in determining lesions, emphysema or hypertrophy of the lungs, pleural adhesions, reciprocal relations of affections of the heart and lungs, initial lesions of pulmonary tuberculosis. These chapters are illustrated by thirty-two figures which are well drawn and are an addition to the text.

In the chapter on arteriosclerosis Tripier discusses the views of other authors, most extensively and most critically those of Huchard, with whom he does not agree. He considers the distinctions which many make between arteriosclerosis and atheroma, but has nothing to add to what is generally known of the causation of the arterial lesions. The frequent association of arteriosclerosis and sclerosis of the kidneys and the common notion of a relationship of cause and effect lead to a general discussion of scleroses, which, Tripier says, "are composed of new tissue of an inflammatory origin." Moreover, he writes further on, "one never sees an arteritis of small arteries more or less extensive preceding the production of the inflammatory lesions, as would be expected if there was an initial causative endoarteritis." Sclerosis is more or less variable in different organs, owing to their varying structure as well as to the age of the subject affected, his habits and his antecedents. It does not suffice to invoke an arterial lesion more or less generalized to explain these diverse changes in organs.

Of the heart lesions in Bright's disease Tripier considers at some length those with and those without sclerosis. This chapter is somewhat polemical, and while in it the nature of arteriosclerosis and of the associated lesions in various organs is discussed, the clinical aspect and the anatomic details of the lesions are not. The author endeavors to establish his own views on observed facts and to avoid the hunt for facts to maintain a hypothesis as so many authors do.

An analysis of each chapter cannot be made here, but what has been said of this one will illustrate the author's method of thinking, though the others deal more with diseases and less with theories than does this one.

CARE OF MOTHER AND CHILD. By Clarence M. Cheadle, M.D., Member American Medical Association. With an Introduction by Charles Edwin Ruth, M.D., formerly Professor of Surgery and Anatomy, Keokuk Medical College, now of Ponce, Porto Rico. Cloth. Pp., 354. Price, $2. Published by the Author, Ashton, Ill., 1909.

Dr. Cheadle has felt the need, as have many other physicians, of a simple, concise, not too technical little treatise that could be placed in the hands of an expectant mother to give her an intelligent idea of the pregnant state, how to conduct herself during this time, how to prepare herself for the important coming event, and how to meet the great obligations that have been placed on her after the baby is born. To meet this need he has prepared the book before us. Dr. Cheadle addresses himself throughout to the mother and rarely forgets himself, as is so commonly done, to introduce prescriptions, formulas and other technicalities. Part I is devoted to the mother, the changes that occur during pregnancy, its signs, symptoms and complications, the preparation for confinement, the event itself and the after-care and convalescence. Part II deals with the baby, its care and hygiene, growth and development, natural and artificial feeding, and its common nutritional disorders. Part III deals with the common diseases of children, giving the mother an idea of their cause and nature, and of the general principles of treatment. The part dealing with infant-feeding is especially noteworthy for the author's familiarity with newer ideas and their exposition. We hope, however, that in a subsequent edition even the few tables for infant-feeding that he gives will be omitted and that the expression "colorimetric method" will be avoided, for even healthy babies cannot be fed by a table or by a "method."

The work has evidently been a labor of love and has a commendable ring of earnestness and of purpose. There is a need of missionary work on the subject of puerperal mortality and morbidity, of criminal abortion and infant mortality. Dr. Cheadle feels his responsibility and meets it in the true spirit. To quote from the preface: "The number of women who die from puerperal causes is so great that it appalls the one who stops to consider. And still the tide of death flows on and few are the hands put forth to stay it. Here is one feeble hand put forth. It is hoped that it may gather in a few from the black tide and restore them again to the places among their children and husbands." The physician will find nothing new in the book, but to the mothers and expectant mothers for whom it was written it can be warmly commended.

The Development of the Chick. By Frank R. Lillie, Professor in the University of Chicago. Cloth. Pp. 472, with illustrations. Price $4. New York: Henry Holt & Co., 1908.

An essential requisite to the understanding of anatomy, either human or comparative, is a thorough appreciation of the facts and processes of embryology. This subject has been taught by laboratory methods in our colleges of liberal arts and sciences for only three decades, and in our medical schools, with a very few exceptions, the laboratory teaching of embryology has been introduced within the last decade. Owing both to the availability of material and also to the fact that the text-book of Foster and Balfour was, for two decades, the only book available in embryology, the greater part of the laboratory teaching of embryology, until very recent years, has been on the chick, and therefore this form has come to be a classic. Now, however, especially in the medical schools, mammalian material is more and more used to illustrate the facts of embryology. For certain phases of development, however, the chick is still a favorite form, and therefore it is of interest to the medical profession to note the appearance of this excellent work, giving a logical and exhaustive treatment of the devlopment of a single animal. In the earlier part of the book the author discusses some of the more general problems of embryology and then takes up the various fundamental processes of the early development of the chick. This is followed by a discussion of the differentiation of the several organic systems. The discussion does not aim to be comparative; Professor Lillie confines himself almost entirely to the phenomena that occur in this one animal and goes into accurate detailed description of this limited subject.

The book is rather too extensive to serve as a text-book for beginners, and especially for beginning medical students who wish to devote some time, at least, to mammalian embryology. The book, however, will be found of the greatest value for reference, and every teacher of embryology must constantly consult it. It will furnish excellent and interesting reading for the student after he has made some headway in embryology. It will serve to stimulate the interest of the practitioner and to give a view of recent advances in this limited field. The accuracy and conservation of the statements in the book may be relied on. The book has excellent and well-selected illustrations, many of which are new. The work of the publishers has been very well done so far as the printing and binding are concerned, but the impressions of some of the figures are not entirely successful. The appearance of this book is of distinct value to the advance of medicine, since it will serve to stimulate the production of a better text-book in mammalian embryology than we now have. From the point of view from which it was written—that is, as a carefully balanced and well digested exposition of our present knowledge of the embryology of this one animal—the book is successful.

Miner's New Complete Obstetric Record. Improved Edition, Giving all Medical Data Bearing on the Problem of Heredity. Cloth. Pp. 124. Copyright, 1883, by Joel A. Miner. Ann Arbor, Mich.: Joel A. Miner.

This book is something in the nature of a ledger, and contains space for the personal history of the father and mother, the history of the labor, description of the child and general remarks regarding the puerperium. It should be of value not only to obstetricians, but to physicians in general practice, as it is an adequate means of keeping complete obstetric records.

Arbeiten aus dem Pharmazeutischen Institut der Universität Berlin. Herausgegeben von Dr. H. Thoms, Professor und Direktor des pharmazeutischen Institutes der Universität, Berlin. Vol. VI. Comprising the work for 1908. Cloth. Pp. 304, with 4 illustrations. Berlin: Urban and Schwarzenberg, 1909.

Dr. Thoms is a corresponding member of the Council on Pharmacy and Chemistry of the American Medical Association and his work in the investigation of synthetic remedies, secret preparations, and other chemical matters of interest to the medical profession is too well and favorably known to need comment. The volume contains reports of investigations of medicines, foods, technical products, colonial products, etc., as well as reports of much original work in pure and applied chemistry. In the section devoted to medicines we have the work of Zernik on the most important new remedies of the year 1908 and investigations of secret remedies by various workers. The work on the new remedies is of vast importance. It puts before the profession an account of the composition and properties of the new synthetics from a disinterested source. References to the literature are appended. An idea of the prolific character of chemical industry is afforded by the list of new remedies for the year which includes 61 titles, of which 14 have been specially investigated in the department. The need of continual watchfulness over accepted remedies is shown by the results obtained by Zernik in studying theobromin preparations; he found that a sample of the theobromin sodium acetate contained less than 40 per cent. of the theoretic amount of theobromin and a sample of theobromin sodium salicylate only 70 per cent. of the theoretic quantity of theobromin.

The Great White Plague: Tuberculosis. By Edward O. Otis, M.D., Professor of Pulmonary Diseases and Climatology, Tufts College Medical School. Cloth. Pp. 321. Price, $1.00 net. New York: Thomas Y. Crowell & Co.

This book is written for the layman and contains the facts concerning tuberculosis, its causation, symptomatology, curability and treatment, its prevention and the world-wide crusade against it. The language is simple and an attempt is made to bring the chief facts regarding the disease within the comprehension of the ordinary layman, while making no attempt to encroach on the proper field of the physician. The book ought to have good influence in helping in the campaign against tuberculosis.

Third Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. Andrew Balfour, M.D., B.Sc., F.R.C.P., D.P.H., Director, Fellow of the Royal Institute of Public Health. Cloth. Pp. 477, with illustrations. Published for Dept. of Education, Sudan Government, Khartoum, by Bailliere, Tindall & Cox, 8 Henrietta St., Covent Garden, London, 1908.

This handsome volume is nearly twice the size of its predecessor, which was issued in 1906. The report includes the work of the staff of the laboratories and also a number of papers prepared by other authors who have done work in the laboratories. Prominent among these papers is one by El Bimbashi Hassan Effendi Zeki describing "The Healing Art as Practiced by the Dervishes." This gives an account of the native medicine before the country came under British control and shows a marked contrast with the modern scientific methods now in vogue. The method of amputation was to draw the limb through a hole in the wall and sever it at one stroke with a sharp sword. The stump was then plunged in boiling oil which checked hemorrhage and the limb was bandaged with calico. This article is supplemented by notes contributed by other authors. An account of trypanosomiasis in the Anglo-Egyptian Sudan is given by the director, Dr. Balfour. There are some interesting and valuable contributions in the field of entomology. A description of the poisonous snakes of the Anglo-Egyptian Sudan is given by Dr. Franz Werner. Helminths are discussed by Robert T. Leiper, M. B. A large section is occupied with the anthropologic results of an expedition made by Mr. A. M. Pirrie, who unfortunately died before he was able to finish his work. The report of the chemical laboratory, in addition to other valuable work, takes up the results of a study of the various gums of the Sudan and their origin, which is now believed to be microbic. The work is handsomely illustrated and will be of special value to those interested in tropical medicine.

CHILDREN IN HEALTH AND DISEASE. By David Forsyth, M.D., D.Sc., Physician to the Evelina Hospital for Sick Children. Cloth. Pp. 362. Price, $3. Philadelphia: P. Blakiston's Son, & Co., 1909.

It has been a pleasure on several occasions in the past few months to comment with especially favorable emphasis on books on children by English authors, notably those of Thompson and of Still. To this the present volume is no exception. The object of the book is to present a concise but comprehensive picture of child life in health and disease, which Dr. Forsyth says, can be seen in its proper perspective only "when we take up our position at the meeting-point of the many sciences that are concerned in the development and welfare of the young." He deals thus in turn with the physiology, psychology, school hygiene and training of the young, with idiocy and feeble-mindedness, infant mortality, children and disease, the examination, diagnosis and some points in the treatment of sick children. The idea is undoubtedly a good one and has been consistently and masterfully carried out—but the space between covers is too small, and under such circumstances the "Psychology of Children," and "Examination of the Vomit and Feces," come so close together that the effect is rather jarring. With so luminous and scholarly an author, one can not help but feel that a more satisfactory book would have been produced if the purely medical chapters on disease had been omitted. and the rest correspondingly expanded. The unity of the book that the author aims at is rather destroyed by bringing in strictly medical technicalities, thus giving the whole a sort of encyclopedia-of-child-life effect.

The book will appeal especially to medical men who are interested in all that pertains to children, and not merely in their ailments, and to the ever-increasing number of intelligent mothers who are looking for help in bringing up their boys and girls to the highest possible standard. Both can well omit the last few chapters, and both will be well repaid for assimilating the rest. The book itself has an appropriately dignified appearance and one is especially favorably impressed by the large, clear type and the restful effect of the thick, cream-colored paper.

AGRICULTURAL BACTERIOLOGY. By H. W. Conn, Ph.D., Professor of Biology at Wesleyan University. Second Edition. Pp. 331, with 64 illustrations. Cloth. Price, $2.00, net. Philadelphia: P. Blakiston's Son & Co., 1909.

The second edition of this well-known work has been revised and somewhat enlarged, but the general treatment has not been materially altered. Many interesting topics are discussed and the book contains information likely to be of a good deal of value to the scientific farmer. The style of writing is on the whole clear, but embellished by too many expressions such as "the disease side of the bacteria story," page 3, and "a little thought will show us," page 55. Not a few errors of fact have crept into the text, as, for example, the statement on page 130 that the presence of *B. coli* in a sample of water "indicates a certainty of danger." Again on page 282 we are told that the spores of the anthrax bacillus will "resist a temperature of about 280 degrees F. for two or three hours." The book, however, is likely to hold the place it has already made for itself in spite of these and other blemishes.

HEMORRHAGE AND TRANSFUSION. By George W. Crile, A. M., M.D., Professor of [illegible] ern Reserve Medical College. Cloth. Pp. [illegible] Price, $5.00. New York: D. Appleton & Co., [illegible]

These papers by Crile and his associates present the data and results of the work of eleven years in research and clinical observation. Much of the material has been previously published, but the convenience of the reader or investigator has been well served by the collection in compact form, with the most complete details, of this large mass of experimental and clinical experience. The literature of the subject is thoroughly considered. Dr. Crile has analyzed the evidence of his own experience and that of others in the most thorough and logical fashion, covering every point, so that, so far as information on these subjects is obtainable, his conclusions represent the most scientific views of to-day. The technic of transfusion is clearly presented and by the improved method of the author reduced to the simplest and most practical form. The book, though large, will amply repay careful study.

Miscellany

Twelfth International Congress on Alcoholism

Dr. Reid Hunt (*Pub. Health Rep.*, Oct. 8, 1909, xxiv. No. 41) reports his observations as delegate to the Twelfth International Congress on Alcoholism held in London, July 18 to 24. Among the great variety of subjects discussed at the scientific sessions were the effect of alcohol on immunity, heredity, muscular and mental energy, its relation to tuberculosis, insanity, nervous diseases and therapeutics. The consensus of opinion of the speakers seemed to be that alcohol, in any form, is seldom of distinct value in the treatment of disease; and some evidence was brought forward to show that alcohol even in moderate amounts has an unfavorable effect on offspring and has a tendency to lower resistance to infection.

The statements frequently made that alcohol is, *per se*, a predisposing factor to tuberculosis received some but not marked support from an elaborate statistical study by Henschen of Sweden.

In discussing a paper by Mr. Wilbert on the alcoholic beverages in the different pharmacopeias Hunt called attention to the fact that only the United States and Greek pharmacopeias include whisky, and suggested that its recognition by these pharmacopeias gave it an undue prominence as a medicinal agent; also that wine is very undesirable as a pharmaceutical agent and that the preparations made with it should be discarded from the Pharmacopeia.

One of the most important of the general meetings was devoted to the subject of alcohol and the efficiency of the national services, at which representatives of the naval, military, postal, railway and legal professions spoke. The extraordinary growth of total abstinence in the British army and navy was especially emphasized; 40 per cent. of the army in India are total abstainers. This growth of total abstinence in the army was attributed to a very considerable degree to the improvements that have been made in the surroundings of the soldier, such as improved housing and food. One speaker pointed out the need of giving much more attention to the physical welfare of the sailors of the merchant marine. The unhygienic conditions under which many of them live were held to be the chief cause of their intemperance and the deterioration caused by these factors (intemperance and lack of hygiene) was called a national danger.

Other features of the congress are described in some detail by Cora Frances Stoddard (*Survey*, Oct. 9, 1909, xxiii, 81).

Dr. T. Laitinen, professor of hygiene at the University of Helsingfors, reported studies in human families which confirmed his long and careful observations on animals, and which showed that the birth-weight and subsequent eight months' development of children of drinkers averaged less in a group of over 20,000 than in the case of children of non-drinkers. Poorer hygienic conditions in home and care afforded by the drinking parent, as well as the alcohol itself, undoubtedly had an influence in producing these results.

Dr. Karl Graeter, a nerve specialist of Basel, Switzerland, gave statistics showing that from 9 per cent. up of the children of moderate drinkers investigated were mentally defective or tuberculous, and from 17 per cent. up of the children of heavy drinkers, as against 5 per cent. of the children of abstainers.

The discussion on alcohol and crime, of course, reinforced the evidence of years as to the close relation between crime and drink. The lord chief justice of England, Lord Alverstone, declared that after forty years at the bar and ten years as a judge, he had no hesitation in saying that in 90 per cent. of the crime in England, drink was a factor. Lieutenant-Colonel McHardy of Edinburgh stated that in Scotland in 1907, there were about 90.000 cases of public disorder due to drink.

The rational explanation of these statements was given by Dr. Legrain of Paris, who said: "Alcohol produces an intoxication which is only a brief attack of lunacy. There is no other term which describes the almost instantaneous disorders which impair the judgment, the reason, and exactitude of sensation, and which destroy the will only to install brute impulse in its place."

Sir Thomas Whittaker, as president of one of Great Britain's largest life-insurance companies, stated that their nonabstainers were so carefully selected that the mortality was less than in other societies. Even then, the records of the company showed a difference in favor of the abstainers of from 25 to 30 per cent., showing their better health and longevity.

Practical dealing with the alcohol problem in the light of the discussions of this congress resolves itself into the essentials of all social reform: popular education as to the perils involved, inculcation of respect for individual and community good, elimination of sources of temptation as rapidly as possible; cure of the victims if attainable; if not, isolation for the sake of public order and public welfare.

Gastroenterocolitis in Infants.—H. B. Sheffield (*Merck's Archives*, July, 1909) is inclined to regard the various gastrointestinal disturbances usually described as "gastritis," "enteritis," "colitis," "gastroenteritis" and "enterocolitis" as mere stages of one and the same pathologic condition, and discusses the subject in question from this point of view. Occasional vomiting and diarrhea, occurring as a result of unusual overloading of the stomach, too hasty feeding, ingestion of indigestible articles of food or foreign bodies, exposure to sudden atmospheric changes and undue excitement, etc., are not rarely observed in otherwise apparently healthy, well-nourished children, and if of brief duration are of no special clinical significance. These attacks may even be accompanied by fever, mild cerebral irritation, colic, etc., and yet remain outside the domain of pathology, or represent an affection which is generally spoken of as simple indigestion or the first stage of *gastroenterocolitis. The second stage of gastroenterocolitis* is generally described as gastrointestinal catarrh or dyspepsia.

Ordinarily, these manifestations set in insidiously, and if not promptly arrested grow worse gradually, arousing little if any anxiety on the part of those in charge of the baby, or are lost sight of, sometimes because of coincident "teething" (with the laity the presumptive cause of all ills) until there is a sudden aggravation of the condition—supervention of the third stage of the disease. In this stage gastroenterocolitis assumes a very acute course. It is manifested by violent vomiting, excessive thirst, frequent, thin watery, brownish, greenish and later colorless or blood-stained stools. The vomitus is acid in reaction, bile-stained and offensive in odor. The bowel movements vary from 10 to 15 in twenty-four hours, and are followed by griping pain and tenesmus. The child is very restless, feverish, sleepless, and, with the symptoms persisting a few days, rapidly loses in weight, and sinks into a state of collapse, followed by convulsions, coma and death.

Closely allied to the gastroenterocolitis just described (though possibly differing as to the exciting micro-organism), and most probably representing only a severer "fulminating" form of the same disease, is the so-called infantile "summer complaint," or cholera nostras infantum. To prevent the graver forms of gastroenterocolitis, promptly remove the causes and effects of the mildest symptoms of the disease. Attention to every detail of rational feeding and personal hygiene are the surest means of prevention. The active treatment should begin with the earliest inception of the gastrointestinal disorder. Regulation of diet is the most efficient therapeutic measure, and is almost invariably attended by improvement in the child's condition, if the treatment is begun with a few hours' starvation of the patient and prompt cleansing of the alimentary tract of its obnoxious contents. Feeding, breast or bottle, should at once be suspended until such time as exigencies for resumption of feeding will demand. In the meantime, especially in the absence of strong contraindications, such as violent vomiting, the infant should receive small quantities of hot or cold, pure water, or a light infusion of black tea. Recurrent vomiting calls for prompt attention. Ordinarily, vomiting can be controlled by "ice-sand," minute doses of calomel with or without bicarbonate of soda or bismuth; bismuth or cerium oxalate; tincture of iodin (in 1/30 drop doses, to be repeated every hour or two); silver nitrate (1/100 gr.); a sinapism to the spine or epigastrium, and, if all else fail, lavage. Lavage should be supplemented by enteroclysis, and, with the vomiting checked, also by a small dose of castor oil. Where diarrhea persists, an astringent mixture like the following is useful:

℞.	gm. or c.c.	
Bismuthi subcarbonatis		
Misturæ cretæ comp.		
Syrupi rhei aromatici		
Glycerini		
Aquæ menthæ piperitæ ... āā	8	ʒi
Aquæ destillata	60	ad. ℥ii

M. Sig.: One teaspoonful every two hours for a child one year old.

The camphorated tincture of opium may be added for the relief of pain. After complete cessation of vomiting, resume feeding, first with small quantities of toast or barley-water, and several hours later diluted cow's milk or breast milk.

In fulminating attacks of gastroenterocolitis, the treatment must be prompt and more heroic. In the initial, febrile stage, after a single but thorough irrigation of the stomach and bowels, the patient is given 1/50 gr. of morphin and 1/500 gr. of atropin hypodermically, is wrapped in warm blankets and sent outdoors. In the algid stage powerful stimulation is in order. Thus a hot bath with brisk rubbing of the body, a hot high enema (injected slowly so as to be retained), hot water by mouth, hypodermic administration of sterile camphorated oil (8 drops of a 15 per cent. solution); strychnin 1/60 to 1/30 gr.; caffein sodium benzoate 1 gr.; or whisky 20 gtts., and hypodermoclysis (1 to 6 oz. of a 0.6 per cent. hot sterile salt solution). As the patient improves, a milder course of treatment is resorted to. Convalescence usually proceeds at a very slow pace, and is frequently interrupted by milder exhibitions of gastrointestinal indigestion, which, if not promptly yielding *to energetic treatment, eventually lead to chronic involvement* of the alimentary tract.

The course of chronic gastroenterocolitis varies in individual cases. At best, the prognosis is very grave (50 per cent. mortality), especially so in infants reared under bad hygienic conditions and in want and misery, and in those born with lowered vitality and congenital constitutional defects. The patient should be removed from the insanitary surroundings and intrusted to the care of some one who would obey orders. Regulation of diet is most essential. A complete cure of gastroenterocolitis in young infants is frequently effected by a prompt change from bottle to breast feeding. The medicinal treatment of chronic gastroenterocolitis is chiefly symptomatic.

Prophylaxis of Recurring Headaches.—H. Hirsch refers to what he calls "habitual headaches," and declares that people are educated into the headache habit unconsciously in many cases, and that effectual prophylaxis is possible. When children see how everything in the household bends on the days when "mother has one of her headaches," they learn to ascribe great importance to headache in general, to seek for it in themselves, and to magnify the slightest ache into "inheritance of mother's tendency to headache." They are thus educated into the headache habit. He sees another factor in the peculiar condition of semiwakefulness as one starts to wake in the morning. This is a close approach to the hypnotic sleep, he says, and the individual actually hypnotizes himself during this intermediate phase between sleeping and actual waking. Who has not had the experience, he exclaims, during this stage of semiwakefulness that the cares of the preceding day come back to the mind with depressing gloom—mole-hills are magnified into mountains and mere possibilities of trouble into malign certainties. If the memory of a headache in the past crops up during this period of semiwakefulness, the dread of the headache hypnotizes the mind into accepting a headache as an actual fact. Massage of the head is liable to induce a kind of semihypnotic condition, against which he expressly warns, and he also advises means to ensure rousing and waking completely as soon as one wakes to semiconsciousness. In his communication on the subject in the *St. Petersburg. med. Wochenschrift*, September 25, he urges the family physician to instruct parents to refrain from paying too much attention to the little aches and pains of their children, and also to tell the parents that—for their children's sake—they must give up the right to their own headaches, that is, they must rise above them, not yield supinely to them.

Medicolegal

Validity of Contract of Assistant Not to Practice in Same Place After Termination of Employment

The Supreme Court of Colorado had, in Freudenthal vs. Espey (102 Pac. R. 280), a suit brought by the latter party, its first case for decision involving the question of the validity of such a contract as the one there, whereby the defendant, employed as the assistant of the plaintiff, agreed that on the termination of his employment he would cease "the practice of medicine, surgery or obstetrics or the branches of either," directly or indirectly, in the city, a place of about 10,000 inhabitants, for a period of five years.

Such contracts, the court says, must have an actual consideration appearing from or in the contract, or, at least, set forth in the complaint. What is termed a legal consideration is sufficient. It will not be inquired whether or not it is adequate, or, in other words, equal in value to the restraint agreed on. Nor will the court inquire whether the defendant in submitting to the restraint made a judicious contract.

In this case the consideration on which the defendant entered into the contract as expressed therein was "the salary and compensation" which would inure to him by reason of the employment and association. The salary was $125 a month. Then there were mutual promises to be performed which were the consideration for each other. The plaintiff was to introduce the defendant to his patients and friends, furnish proper conveyances, and in return the defendant was to exert his skill and attend to the professional business of the plaintiff and "earnestly endeavor to increase and built" it up. It was certainly of great benefit to the defendant, an inexperienced professional man, to be associated with a capable and efficient member of his own profession, long experienced, and enjoying an extensive practice. The public were likewise benefited, locally, in having the inexperienced practitioner under the direction of, and guided by, one skilled in his profession, and equally so would the public elsewhere be benefited when he engaged in his profession for himself. The court is clearly of the opinion that the facts of this case disclosed a sufficient legal consideration.

Taking up the next question of whether the contract was reasonable, the court says that agreements like this must be construed with reference to the objects sought to be attained by them. The object here was the protection of the plaintiff against competition in his profession. The nature of the business to protect was a medical practice extending far beyond the limits of the city. He possessed this business and the knowledge and the skill that enabled him to acquire it. Certainly in limiting the restriction to the city and for the period of five years was only affording a fair protection to the interests of the party in favor of whom it was given, and not so large as to interfere with the interests of the public. The restraint was no larger than the needs of the plaintiff required. It was of material benefit to him and was not oppressive on the defendant, nor was it in any sense injurious to the public. The contract was in no wise forbidden by any principle of policy or law. The defendant could be as useful to the public at any other place as in the city in question, and the interests of the community elsewhere were as important as they were there. Here the defendant had no business, was inexperienced and presumably unskilled, and desired and sought the benefits that would accrue to him by association with one so learned and skilled in his profession as the plaintiff. It is a known fact that professional skill, experience, and reputation constitute part of the individuality of any particular person, and the amount of business which such person does depends largely on the confidence reposed in him personally as a professional man. Under such circumstances it is not to be presumed that one whose personal excellency and skill have brought him a profitable business will take another in, and by vouching for such other's skill and honor endear him to his own patients and leave such other free to steal away his profits.

The circumstances under which the defendant entered into the employ of the plaintiff here were such as to justify the latter in asking him to enter into some agreement of the nature of that involved in this suit. It was of importance to the plaintiff to exact of the defendant a covenant which would prevent him on the termination of the service for utilizing the knowledge and experience he had gained by such service in destroying the plaintiff's business. It was reasonable and proper. Besides, the court is not disposed by judicial decree to render it practically impossible for the unlearned to better their condition, and become skilled in a trade or experienced in a profession, by means of proper apprenticeships, as it would do, were it to declare this contract void. Few professional men would take assistants and intrust them with their business, impart to them their knowledge and skill, bring them in contact with their clients and patients, unless they be assured that the knowledge and skill imparted and the friendships and associations formed would not be used, when the services were ended, to appropriate the very business such assistants were employed to maintain and enlarge.

A distinction exists between that class of contracts binding one to desist from the practice of a learned profession and those which bind one who has sold out a mercantile or other kind of business and the good will therewith connected, not to engage again in that business. In the former class there should be a reasonable limit as to time so as to prevent the contract from operating with unnecessary harshness against the person who is to abstain from practicing his profession at a time when his so doing could in no wise benefit the other contracting party. In the latter class such limit is not essential to the validity of the contract, but the restraint may be indefinite. The contract in this case met the requirements of this rule.

Entertaining these views, the court affirms a decree in the plaintiff's favor, enjoining the defendant from doing what he agreed not to do.

Validity and Construction of Illegally Limited License—Right to Verification License

The Court of Civil Appeals of Texas says, in Board of Medical Examiners of Texas vs. Taylor (120 S. W. R. 574), that the board refused Mrs. Taylor's application for the verification license required by the medical practice act of 1907 to practice medicine, tendering her instead one to practice "obstetrics only." This was based on the fact that her original license, issued by a district board of medical examiners in 1889, used the words, "branches of obstetrics and diseases peculiar to women and children." But the district board certified that it had examined the applicant "as required by the laws of the State of Texas," and was "satisfied" as to her "qualifications," while it was duly established that from such time she had been a legal and regular practitioner of medicine, in general practice in the state.

Under these circumstances, the court considers that she was entitled to a writ of mandamus to compel the issuance of a verification license "to practice medicine," without the limitation sought to be imposed on her. It says that it does not think that in the facts admitted and by giving proper effect to the entire language of the certificate that the words in the certificate, "branches of obstetrics and diseases peculiar to women and children," were intended, or should be so construed, by the board to declare that they were not "satisfied" as to the applicant's qualifications in the requirements of the law. If the board intended by the words just mentioned to designate in the certificate the branch or department of medicine that she was to practice, any such designation would have no legal force or effect, would be surplusage, and would not affect her legal rights in the premises. So the fact, appearing from the certificate and admitted, that she appeared before the board, not as an applicant to practice midwifery or obstetrics only, and bearing in mind that the board was not authorized to give certificates "to females practicing midwifery exclusively," and it appearing that the board intended to and did act within its legal authority, it follows that the court would not be justified or warranted in construing the certificate in question to be a certificate intended to certify the right to practice obstetrics only.

Holding as the court does, that the legal effect of the certificate granted to the applicant by the district medical board was to authorize her "to practice medicine under the laws at the time in force, it follows that she was entitled to a verication license at the hands of the state board as broad as the legal effect of her certificate, which, by force of the law, was "to practice medicine." The duty of verification imposed on the state board by the law is to confirm or substantiate something already done. The power involved in the verfication extends to the ascertainment of the genuineness and valid existence of the license previously by law granted by authorized board, and the identity of the person claiming and presenting the same, there being no cause as defined in section 11 of the act authorizing a refusal to issue.

Current Medical Literature

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York

November 13

1 *Diabetic Coma: Is It Due to Acidosis? H. S. Stark, New York.
2 *Treatment of Amebic Dysentery. W. E. Deeks and W. F. Shaw, Ancon, Canal Zone.
3 Surgical Treatment of Severe and Late Cases of Amebic Dysentery. A. B. Herrick, Ancon, Canal Zone.
4 *Pathogenesis of Tabetic Arthropathies Based on an Anatomic and Clinical Study of Two Cases. A. Gordon, Philadelphia.

6 Twenty Cases of Pulmonary Tuberculosis without Bacilli in the Blood. L. Rosenberg, Bedford Station, N. Y.
7 Wrist Support for Sphygmographic Tracing. D. Felberbaum, New York.

1. **Diabetic Coma.**—Stark is opposed to the assumption that the coma is due to acidosis, because: 1, A decided acetonuria occurs in the course of numerous diseases of widely different characters, *e. g.* gastrointestinal disorders of childhood (cyclic vomiting), acute yellow atrophy of the liver, eclampsia, pernicious vomiting of pregnancy, intoxications from metals and anesthetics, etc. 2, Acidosis may occur in health on a continuous sugar-free diet, and also during physiologic starvation, and during inanition from wasting disorders, such as carcinoma and tuberculosis. 3, Adyspneic coma, not unlike true diabetic coma, is encountered in other diseases than diabetes, such as measles, scarlet fever and typhoid. Save for the presence of dextrose in the urine, these comas could not be clinically differentiated. 4, Diabetic coma may occur without acidosis, but with a large ammonia excretion. There are quite a number of such cases recorded in literature and they have an important bearing on the question of the origin of coma. 5, Alkali therapy has been notoriously a failure, either as a prophylactic or as a curative measure. Stark believes that the failure of alkali medication, either to abort or to tide the patient over an attack, seals the fate of the acidosis theory.

2. **Treatment of Amebic Dysentery.**—The rest-supportive treatment, consisting of rest in bed, a milk diet, the use of mild irrigations and bismuth subnitrate in heroic doses, has given Deeks and Shaw by far the most satisfactory results. Surgical interference, they say, is indicated if improvement does not rapidly follow the above-mentioned method.

4. Abstracted in The Journal, July 31, 1909, page 405.

5. **Heart Disease.**—This is an elaborate statistical analysis of the subject.

18 *Vaccine Treatment of Lobar Pneumonia. T. Leary, Boston.
19 Immediate Results and Surgical Complications of Gastroenterostomy. F. T. Murphy, Boston.
20 Physiologic Aspects of Gastroenterostomy. W. B. Cannon, Boston.

18. **Vaccine Treatment of Lobar Pneumonia.**—Believing that the data obtained from the treatment of cases of alcoholic pneumonia would at least be suggestive, Leary appealed to several medical groups to test the value of vaccine on the alcoholic and extreme cases. Pneumococcus vaccine was furnished for the treatment of 34 patients of this type, of whom 6 died (17.7 per cent). In a larger series of cases of ordinary pneumonia (49), 15 per cent. came to crisis in three days, and but 2 deaths were reported. The total deaths for the series of 83 cases were 8, or 9.7 per cent. It was noted by most observers that rapid relief of toxemic conditions, which were present in serious cases, followed the use of vaccine, and in cases of uncontrollable delirium an abatement of the delirium was prompt. The results are encouraging enough, Leary believes, to justify the wider application of this treatment. For the purpose of obtaining data from a sufficient number of cases to furnish material for definite conclusions, a fund has been established through the munificence of public-spirited citizens in Boston by means of which pneumococcus vaccine will be furnished without cost for the treatment of lobar pneumonia.

28 No Free Hydrochloric Acid in the Stomach. J. Ballagi, Homestead, Pa.

23. **Orcheopexy.**—The operation devised by Torek is performed in the following manner: The testicle is exposed through an incision over the inguinal canal. The aponeurosis of the external oblique muscle is split to the same extent as in the operation of inguinal hernia. Testicle and cord are freed from all their coats. As regards the testicle, Torek is of the opinion that it is a decided advantage to liberate it by turning back its tunica vaginalis, as direct attachment to the fascia of the thigh is doubtless firmer than if the tunica vaginalis were interposed. The vas deferens and the vessels of the cord must be denuded of all their coverings. The gubernaculum testis is removed, so that nothing remains of the cord but the vas deferens and the blood-vessels, and these should be separated from all surrounding connective tissue to a point high up behind the abdominal parietes. Should any vessel exceptionally prevent the testicle from being drawn down, it may be divided.

The next step is to make an incision in the thigh to expose the fascia lata. The site for this incision is determined by taking the testicle out of the inguinal wound and drawing it down gently. The point at which it touches the thigh is chosen for the incision. The direction of the incision is from in front backward and slightly downward, thus coinciding with the natural lines of the skin. A pocket is made by gently digging with the finger from the lower end of the inguinal wound through the loose connective tissue to the bottom of the scrotum. Here the pocket is opened by an incision, which must correspond in length and direction precisely with that in the thigh, in order that the cut edges may be united evenly, without tension and without folds. The testicle may now be drawn down through the newly formed canal and be made to emerge from the scrotal wound. Or it may be left above until one is ready to suture it to the fascia. In that case, however, the canal should be kept open by inserting an instrument or a strip of gauze through it. Torek prefers this because the testicle being left above, is out of the way during the next step of the operation, the union of the upper edge of the thigh wound to the corresponding edge of the scrotal wound.

The next step is fastening the testicle to the fascia of the thigh. From three to five sutures of chromicized catgut are inserted, the number depending on the size of the organ. Enough of the tunica albuginea must be caught in the sutures to give a good hold. All sutures are inserted before any are tied. When the sutures between testicle and fascia have been tied, the anterior lip of the scrotal wound is sewn to the lower edge of the thigh wound. This suture is simple; but one must remember the tendency of the scrotal skin to turn in and must counteract it. The testicle is then completely covered by skin. The inguinal wound is closed in three layers, as in Bassini's operation for hernia, with the difference that the cord is not displaced, unless the simultaneous presence of a hernia renders this procedure desirable. In that case the deep suture, that uniting Poupart's ligament with the internal oblique and transversalis muscles and their tendon, is made before the testicle is brought down through the scrotum. In all other cases the cord is allowed to come down in the shortest and most direct way. The operation is now completed. With the aid of a dressing forceps a small strip of gauze is drawn carefully through the canal of skin between scrotum and thigh. It serves as a dressing for the deep suture. A large dressing is then applied covering the entire scrotum and the abdominal wound. This is changed after about six days, when all skin sutures are removed, except the hidden, inaccessible row of stitches between the scrotum and the thigh. After from three to six months the testicle is detached carefully, the scrotal wound closed over it, and the wound in the thigh is also closed.

24. **Central Dislocation of Femur.**—By central dislocation of the femur is meant fracture of the acetabulum with dislocation of the head of the femur into the pelvic cavity. In the literature most of the cases of this character are reported under the head of fractures of the acetabulum. From Halstead's point of view, the presence of the femoral head in the pelvic cavity is the most important element in these injuries. He reviews the literature and reports one case.

42. **Stone in the Ureter.**—This paper emphasizes the diagnostic value of the Roentgen ray in cases of stone in the ureter.

43. **Diseases External to Bladder.**—Schmidt presents the following original classifications: (1) Bladder symptoms due to constitutional or general diseases which are common to both sexes; (2) bladder symptoms due to diseases of neighboring organs or other urinary organs, which are common to both sexes; (3) bladder symptoms due to physiologic or pathologic conditions of the female genitalia, and hence present only in the female; (4) bladder symptoms due to pathologic conditions of the male genitalia, and hence present only in the male; (5) bladder symptoms due to primary pathologic conditions of the bladder itself, common to both sexes.

45. **Foreign Body in the Male Bladder.**—The patient, male, aged 28, was in the habit of introducing a small candle into the urethra. The foreign body slipped from his fingers beyond reach, and passed back into the membranous urethra. In attempting to extract the candle he forced it deeper back until the last attempt forced it up into the bladder.

46. Abstracted in THE JOURNAL, June 19, 1909, p. 2020.

48. **Action of Coal-Tar Anodynes.**—Speaking of the pharmacology of some of the popular combinations, Fantus says that first and foremost in popularity is the combination with caffein, usually in the proportion of one part caffein to three parts of the coal-tar derivative. The caffein is supposed to antagonize the collapse action. That it is not very successful in this respect is evident from the fact that just such combinations as are found in bromo-seltzer, antikamnia, etc., have repeatedly produced death. Perhaps the main reason for the popularity of this combination lies in the fact that caffein has a specific action in temporarily overcoming fatigue and the symptoms produced by it, such as the aches and pains of nerve-tire. In just such pains the coal-tar anodynes are also of value. A combination of the two undoubtedly acts with greater force in cases of this kind than either remedy alone. We must not forget, however, that caffein produces wakefulness. Therefore, this combination must not be used in the thoughtless manner in which it has so often been employed in the past. It is especially indicated in fatigue disturbances; it is especially contraindicated in insomnia and in conditions of excessive nervous irritability. Combination with a bromid is likely to be of advantage in the last-mentioned condition.

56. **Effect of Shaking on Proteolytic Ferments.**—Shaklee and Meltzer have studied the effect of shaking in partly-filled bottles, laid horizontally, on the action of proteolytic ferments. The more essential result of their experiments is that shaking may destroy the three ferments, pepsin, rennin and trypsin; that these are destroyed more rapidly at higher

than at lower temperatures; that trypsin is more easily destroyed than pepsin, and that the shaking produced by the respiratory movements is capable of causing some destruction of the ferments. The experiments showed that the inactivity of the ferment was not dispelled by standing, *i. e.*, it was not a mere inactivation. Recent experiments by other investigators show that other ferments also may be inactivated by shaking. Numerous older experiments have established that shaking is capable of influencing, fundamentally, bacteria, yeast, red blood cells and echinoderm eggs. The authors asume that ferments are organized substances, possessing a certain structure which may be destroyed by shaking. They consider that the action of each ferment is due to a specific vibration which it undergoes in response to shocks derived from the outside and which is made possible by its specific structure. Too vigorous shaking by destroying this peculiar structure makes the continuance of the specific vibration impossible.

58. **Nuclein Synthesis.**—McCollum, after feeding experiments on rats, comes to the following conclusions: The palatability of the ration is the most important factor in animal nutrition. Without palatability, the ration may possess all the necessary food ingredients and yet fail to nourish an animal properly. The failure of previous efforts to maintain animals on a mixture of relatively pure proximate constituents of food-stuffs was due to lack of palatability of the mixture. When sufficient care is given to changing the character and flavor of food supplied in such simple mixtures, it is possible to induce an appreciable amount of growth. Very young animals adapt themselves to a ration possessing a low degree of palatability much better than do adults. Other things being satisfactory, all the phosphorus needed for the growth of the skeleton, nuclein, or phosphatide formation, can be drawn from inorganic phosphates. The animal has the power to synthesize the purin bases necessary for its nuclein formation from some complexes contained in the protein molecule, and does not necessarily use purin bases of exogenous origin for this purpose.

59. **Elimination of Barium.**—Meyer finds that barium injected parenterally is not eliminated to an appreciable extent in the urine but passes out with the feces.

67. **Action of Leucocyte Extract on Pneumonia.**—Aqueous extracts of rabbits leucocytes were used in the treatment of pneumonia in man. Harmful action was not observed in any of the cases and the authors "feel that where a case of pneumonia is treated early with extract of leucocytes, and full and frequent doses given where they are required, this may prove of considerable therapeutic value."

69. **Sera in Tuberculin Cutaneous Reaction.**—The results of Pickert and Löwenstein to the effect that sera of patients tolerant to large doses of tuberculin possess the power of inhibiting cutaneous tuberculin reaction, appear to be confirmed.

73. **Tumors in Wild Rats.**—In 100,000 rats examined in the Federal Plague Laboratory at San Francisco from June 1, 1908, to May 15, 1909, 103 presented tumors suitable for examination, many being adenomas and a few typical carcinomas.

74. **Changes in Elastic Fibers of Aorta.**—The elastic fibers in the aorta require from thirty to thirty-five years to reach their full development. After about thirty-five years there is a quiet period for about fifteen years during which no developmental changes take place. After this time degenerative changes of greater or less extent are seen in the elastic fibers.

81. **Intestinal Anastomosis.**—As the result of experiments which have extended over a period of two years, Georg concludes that the method of Parker and Kerr is the most practical for end-to-end anastomosis, and that of Capek for lateral anastomosis and gastroenterostomy.

82. **Surgical Relations of Intestinal Gases.**—Davis has found in his clinical work that postoperative tympany and trouble in securing intestinal evacuations have decreased in proportion to the care used in keeping the operating room warm and the exposed coils of intestines protected by gauze pads wrung out of hot normal salt solution. Even the slighter abdominal sections done with equal care in handling, but in a cool operating room, and without the protection of hot pads, have been followed by a stormy period of tympany and other disagreeable symptoms which accompany this condition.

Postoperative treatment should be as simple and natural as possible. There should be no starvation, unless the stomach or small intestine is in a condition to prohibit food, but also no forced feeding at first. The weakness which follows denial of all food, and the discomfort and disgust of too much should alike be avoided. Water given as soon as the patient calls for it has been found greatly to promote comfort and a feeling of well-being. It also seems to encourage postoperative peristalsis. Something to promote early restoration of peristalsis is of great importance if a patient would pass a comfortable convalescence.

For fourteen years Davis has made a routine use of strychnin hypodermically after operations, not so much as a heart stimulant as to encourage peristalsis. When it was first made use of it was a matter of frequent remark in the hospital that trouble from postoperative tympany was of rare occurrence. Of late, cases that give trouble from unusual accumulation of gas have been treated with salicylate of eserin in doses from 1/60 to 1/40 gr. hypodermically. Its use has been followed often by an early passing of gas and there can be no doubt that it promotes peristalsis to a remarkable degree and is of great use when the tympany is due solely to muscular atony. An absolute contraindication to the use of eserin is mechanical obstruction and it should be avoided just as one avoids cathartics when mechanical obstruction is present. When rightly used, eserin is an important advance in the treatment of atonic tympany.

Davis says that the points that practical surgeons need especially to have in mind are (1) to have as little fermentable substance as possible in the intestines before operation; (2) to do as little as possible during the operation which will interfere with the normal circulation in the intestinal wall; there should be a minimum amount of handling and resulting trauma; (3) to leave the intestines in the best condition for active peristalsis; long exposure and much cooling are inimical to active peristalsis.

91. Nutrition During Pregnancy.—Davis emphasizes the fact that food therapy in the toxemias of pregnancy is a factor of utmost importance as a preventive as well as a remedial measure. A high fat content is demanded in periods of enormous growth. In certain specific periods of growth a high proteid percentage is safely metabolized. A constant carbohydrate content must be obtained regardless of the proteid and fat proportion. In acidosis a high or almost exclusive carbohydrate diet for a short time is very efficacious.

95. Life Insurance "Urine Examination."—Harrower says that the examination of the urine, and especially that made for the benefit of life-insurance companies is altogether too crude, and not nearly extensive enough. Because of this individuals are being refused life-insurance who would make excellent risks, and, on the other hand, others are "passed" who are by no means what might be called healthy, and, in fact, are in a serious condition. The examination should be made by such as are skilled in this work and should be paid for accordingly. Three dollars is not an unreasonable figure.

105. Suppuration of the Labyrinth.—Recently most exhaustive tests have been applied to these cases to determine if the labyrinth of the affected ear was in any way functionating. The Barany tests were negative in all cases for the operated ear. The hearing tests were uncertain. Until the Voss test for eliminating the normal ear was used, it was impossible to determine if a certain degree of hearing did not exist in the operated ear of all these patients. Page is of the opinion that all reported cases in which it is claimed that any degree of hearing remains after removing a part of the cochlea is a mistake, and that if the Voss test for eliminating the normal ear is applied to these cases it will convince the operator that complete destruction of hearing always follows the removal of any part of the cochlea.

107. Status Lymphaticus.—Harris' patient had an enlarged thymus, weighing 18 grams, which accounted for all the symptoms produced. There was the convulsion with pallor, followed by the intense cyanosis. There was, however, no tracheal stenosis, and the death, as shown by autopsy, was undoubtedly of cardiac origin.

109. Taking Cold.—Kyle divides the condition of taking cold into three classes: First, actual cold; taking cold; acute rhinitis. Second, an underlying systemic condition which produces some local manifestation and irritation in the mucous membrane, predisposing the individual to taking cold. Third, an underlying systemic condition in which the patient has not taken any cold, but the symptoms produced in the mucous membrane are those of a cold. Therefore, the expression "taking cold," as so frequently used by patients and sometimes by medical practitioners, is in many cases a misnomer. The practitioner of special medicine so often sees the individual with a condition resembling a cold in which there is no history of exposure nor usual systemic phenomena, and yet, to all intents and purposes, the patient is suffering from a cold in the head, or has taken cold. Review of the systemic conditions which bring about irritation of the mucous membrane which resembles taking cold, show that in a large percentage of cases of so-called cold in the head, no one remedy can be applied, and that the individual must be studied as carefully for the predisposing cause or underlying element as though typhoid or a beginning pneumonia were suspected.

The individual study of cases enables the physician to apply his remedial agent scientifically and not empirically prescribe a "cold" remedy. Kyle's experience has been that out of 100 persons presenting themselves for relief of what they call a cold in the head, or having taken cold, or frequently taking cold, at least 80 per cent. belong to the class of the systemic condition, either constitutional, organic, or chemical.

112. Aural Complications in Exanthemata.—Borden urges that general practitioners should regard aural discharge as a menace to hearing, and occasionally to life, and not as a more or less common complication without special importance. In a series of 1,164 cases previously reported by Borden in children up to 16 years of age, having aural diseases, 31.6 per cent, had chronic purulent otitis media of long standing.

125. **Headache.**—The following classification of headache is offered by Shiels:

I. FUNCTIONAL HEADACHE

A. TOXEMIC HEADACHES

(1) *Acute*

1. Specific infectious (fevers) frontal or general, seldom vertical or one sided. Increased by congestion.
2. Acute nephritis [illegible] uremia.
3. Acute composite [illegible] th acetone bodies).
4. Puerperal states [illegible] preseptic.
5. Acute drug poisc [illegible] oglycerin, etc.

(2) *Chronic* (Including products of defective metabolism):

1. Kidney headache. From slight neuralgic type to severe with high grade arteriosclerosis. D.D. when severe with albuminuric neuritis from cerebral tumor.
2. Gouty headaches. May be a severe "plus tension" headache or mild "minus tension" headache
3. Malarial headache, neuralgic in type, "brow ague." Short intermissions.
4. Rheumatic headaches common in childhood and associated with "school pressure." Frontal.
5. Syphilitic.
6. Sluggish liver headache associated with constipation.
7. Cirrhotic liver headache (more complicated than No. 6).
8. Constipation headache, without liver associations. (Also reflex.)
9. Intestinal dyspepsia headache, with or without constipation. (Also reflex.)
10. Gastric dyspepsia. (Also reflex.)
11. Gluttony of fats, proteids, or carbohydrates, i. e., acid products.
12. Slow drug poisoning, *e. g.*, arsenic, lead, etc.
13. Noxious air, etc.

B. NEUROPATHIC

1. Emotions and other psychic faults. (Hyperemic.)
2. Migraine (typical), two types, tonic or paralytic, but generally combination.
3. Recurrent or periodic headache without visual phenomenon.
4. Simple neurasthenic headache. (Not sharply defined, "cephalic sensation.")
5. Traumatic neurasthenic headache. (Generally sharply defined.)
6. Epileptic with or without fit.
7. "School pressure" headache.
8. Premenstrual headache other than migraine.

C. REFLEX

1. Errors and disorders of eye, ear, nose, throat and mouth. (When recurrent usually neuropathic, frontal sinus.)
2. Gastric, including hunger and fasting, hyperesthesic, scalp areas, temporal and parietal (D7 and D8).
3. Thoracic and hyperesthesic; scalp area, midorbital and fronto temporal (D4 to D7).
4. Abdominal and hyperesthesic skin areas, occipital, parietal, vertical and temporal (D7 to D10).
5. Migraine (anemic and hyperemic).
6. Periodic other than migrainous.

II. ORGANIC

1. Inflammations within: Encephalitis, local or diffuse from any [illegible] many of the above.) Leptomeningitis [illegible]
2. [illegible] Sinus disease. Bone disease (includ- [illegible] s, etc.).
3. Arterial degeneration (see chronic toxic headaches).
4. Tumors (including syphilis, tubercular cysts, etc.), severe, dull or acute, constant with paroxysmal attacks. No definite position unless superficial, preventing sleep. Intracranial pressure augments, vertigo, optic neuritis, etc.
5. Indurative (see toxic).

III. CIRCULATORY

A. Anemic, slowly produced; majority "minus tension" headaches; controlled by position and alcohol.

1. Systemic (convalescence).
2. Blood dyscrasias.
3. Cardiac debility.
4. Consequent on pressure.
5. Consequent on spasm.

B. Hyperemic, majority "plus tension."

1. Heart hurry (exophthalmic goiter, etc.).
2. Cold, etc. (peripheral spasm).
3. Drugs, nitroglycerin, etc.
4. Sunstroke (excessive heat, alcohol, anger).

C. Passive Congestion, "mechanical headaches."

1. Mitral and other head lesions.
2. Mediastinal tumor.
3. Persistent cough.
4. Faulty attitude in sleep.
5. Collar restrictions, etc.

127. **Nephritis with Unusual Features.**—Harry's cases are interesting from the fact that, although the patients were all comatose before they died, none of them had any muscular twitching or convulsions. One case was remarkable from the fact that the patient lived six days with a total secretion during that time of from 4 to 6 ounces of urine. She was perfectly conscious until the night before she died, and did not complain from anything except the soreness of her gums from ulceration.

134. **Nitroglycerin in Chronic Myocarditis.**—In Ward's experience, one-drop doses of 1 per cent. solution of nitroglycerin, given with digitalis, every two or three hours, are practically inert; but if from 1/20 to 1/10 of a grain be given every minute, for twenty or thirty doses, brilliant results will be obtained, days before the effect of digitalis can possibly be expected. In edema of the lungs the toleration for this drug is most extraordinary, and relief from dyspnea is uniformly obtained before the physiologic effects, such as flushing of the face and throbbing headache, are produced. Ward reports two cases of myocarditis with cardiac failure and edema of the lungs, one without and the other with valvular lesion, in which nitroglycerin was of the greatest service.

135. **Thymus Death.**—Kirk reports 2 cases with autopsies. Case 1, a boy aged 18 months found dead in bed. Thymus; greatly increased connective tissue, very slight fatty change; increase in lymphoid and large polyhedral cells. Case 2, sudden death after illness of two hours' duration. Enlargement of thymus; enlargement of mesenteric glands (lymphatic); hypostatic congestion of both lungs.

9 Congenital Pyloric Stenosis Successfully Treated without Operation. E. M. Pearse.

1. **Hernia of Uterus in Men and Women.**—Bland-Sutton has collected many instances in which men with incompletely developed external genital organs have been brought up as women, and late in life suffered from strangulated hernia. Bland-Sutton says that it sometimes happens that herniotomy is performed on a child with normal female external genitalia, the surgeon removes a rounded grandular body from the inguinal canal, which he believes to be an ovary, but on microscopic examination it proves to be a testis. The most remarkable cases are those in which the surgeon performs an operation on a man with well-formed external genital organs for the purpose of removing a tumor from the scrotum, but the suspected tumor proves to be a uterus.

2. **Hemolytic Power of Serums.**—Embleton and Shaw succeeded experimentally in developing in the serum of animals, into which injections had been made of the organs of another animal of the same species, a change which consists in part at least, in the increase of the hemolytic power of the serum. Further, the emulsions of different organs appeared to have different powers of checking the hemolytic property of such experimental serums, the kidney possessing the greatest and the liver the least power, while the spleen and heart occupy an intermediate position, and are equally or nearly equally potent.

4. **Fulminating Appendicitis.**—According to Butler, the fulminating cases of appendicitis are due to the formation of a volvulus of the appendix, which is thereby strangulated, and the toxemia and localized peritonitis, which mark ordinary cases of appendicitis, are not present. Gangrene supervenes rapidly, and there is no time for adhesions to form and to shut off an abscess. General septic peritonitis, therefore, ensues if an operation is not performed in the first few hours after the onset of the pain. Volvulus of the appendix may, he thinks, develop in any case in which the appendix lies free in the abdomen, but not when it lies in the retrocecal fossa.

5. **Pneumococcus Invasion of the Throat.**—Peacock reports a case of this kind which was followed by pleuropneumonia and appendicitis. Operation was performed and the patient recovered.

6. **Whitehead's Operation for Hemorrhoids.**—After twenty years' experience with various operations for the cure of hemorrhoids, Bishop recommends Whitehead's operation as at once the most effective, the least painful, and the safest method, but it is necessary for success that certain precautions should be taken beforehand, and that the technic should be carried out very carefully. The intestinal tract should be previously cleared as much as possible. It is not only annoying, he says, but distinctly detrimental to the work, if large masses should make their appearance in the rectum during the ensuing week. Probably the best method of insuring their absence is the administration on the day but one before, of an ounce of castor oil, the taste of which may be disguised by an admixture with it of 2 drams of tincture of cardamom. On the day before operation, the action of this should be supplemented by a copious enema of soap and water, so that the rectum may be clean. At the operation itself another free douche of weak permanganate of potash solution should also be used during the process of dilatation.

Free dilatation of the sphincter should be done before any cutting is commenced. It should be gradual, plenty of time being taken over it, so that no tearing of the muscle is possible. During the operation any actively spurting vessel should be tied, but venous bleeding may be ignored; this bleeding is sometimes free, but will cease as soon as the operation is completed.

Hundreds of patients have been so treated by Bishop without any mortality, and in all with a speedy convalescence. In a few—possibly 2 per cent.—spasmodic urinary retention for a few hours occurred, and, in still fewer, pain at the anus has been complained of, but both speedily yielded to hot boric acid fomentations applied to the part. Catheterism has never been required and, although hemorrhagic discoloration has been seen in a few instances, suppuration or abscess has never followed. Recovery has, in the great majority of cases, been singularly uneventful, and in all complete.

7. **Operation for Hemorrhoids.**—Anderson claims that the Whitehead method should not be employed in all cases of hemorrhoids and that it is indicated in the following conditions: (a) When there is a general hemorrhoidal condition involving the whole circumference of the anal canal, and especially if there is a good deal of prolapse, and also in cases in which there is extensive thrombosis. (b) In cases in which, though the piles may not be large, there is a pathologic condition which may be described as a prefissure or a prefistula state. In this condition the anal valves are enlarged, and curious little blind submucous pockets may be found running for a varying length upward. In other cases these pockets run downward toward the anal margin.

17 Endemic Cerebrospinal Meningitis Treated by Intraspinal Injections of Flexner's Serum; Recovery. D. D. Rosewarne.

11. **Legislation in Regard to Anesthetics.**—That legislation is necessary before the administration of anesthetics can be placed on a safe basis is the contention made by Hewitt. He points out that there is too much single-handed anesthetizing and operating done, especially by dentists, and that this is, in large part, responsible for the mortality from anesthesia. He presents the draft of a bill which proposes to make it a penal offense for any person other than a legally qualified medical practitioner to administer either a general or a local anesthetic. Such a step would also encourage physicians to specialize in anesthesia, which would be most desirable for all parties concerned.

13. **Perforation of Gastric and Duodenal Ulcer.**—Thirteen patients with perforation of the stomach and duodenum were seen by Andrew within a period of nine months. One patient with gastric perforation came to the operating table on three separate occasions; 10 of the cases were gastric and 3 were duodenal. The ages ranged from 16 to 72 years. The average age over all was 37.7 years. The average age of the gastric patients was 36.8 years, of the duodenal patients 41 years. Of the 10 gastric cases only 3 occurred in females, whose average age was 19 years. The 3 duodenal perforations were in men. In 12 of the 13 cases the onset might be said to be instantaneous; in one the onset was more or less subacute. In the majority no food had been taken for some time previously, and the time of perforation was oftenest in the late hours of the evening or in the early morning. In 8 there was definite history of pain after food and other gastric symptoms; in the remaining 5 no history of previous gastric trouble was obtained. In every case of this series pain was a prominent feature, but was quite impossible to define, except that it was severe, "doubled him up," "made him cry out," etc., and was equally difficult to locate apart from surface tenderness. The patients were so ill that speaking was an additional agony and as little as possible was said and indeed asked. In 6 cases, however, the pain was definitely referred to the epigastrium, in 3 others, the pain began around the umbilicus, remaining there in 1, and in the other 2 becoming epigastric later. In 2 the pain was felt in the shoulders as well as in the abdomen—both gastric—so that in 9 out of 13 cases the pain was referred to the upper part of the abdomen. Vomiting subsequent to the onset was stated to have occurred in 7 cases. Collapse was a prominent feature in most of the cases, depending on the length of time since the onset.

Appearance in most cases was indicative of severe pain; the patient looked very ill; the face was pale with malar flush. Distention was definitely present in 4 cases. Rigidity of the abdominal wall, with one exception, was present in every case. In 11 of the cases the rigidity was general, in 2 it was epigastric, but in every case it was more than evident over the stomach. In one case the main rigidity was found on the right side; in another the contraction of the recti was visible. The earlier the case the greater was the rigidity. In the only case in which it was stated to be absent nearly sixty hours had elapsed from the time of onset, and the general peritoneal cavity was found to be shut off. Tenderness, abdominal, on palpation, was present in every case but one, and in that case there had been tenderness which had passed off, and as this patient was seen within a few hours after perforation the tenderness from peritonitis had not had time to manifest itself; the ulcer, moreover, was on the posterior wall. In 6 cases there was epigastric tenderness only; in the remaining 7 it was general, with perhaps a greater degree of tenderness in the epigastrium. In 10 cases there was some alteration in the liver dulness; in 3 cases the liver dulness was completely gone, in 7 it was encroached on, and in 3 cases the liver dulness was normal. Signs of free fluid in the abdominal cavity were obtained in 6 cases. The length of time between onset and operation varied from four and a half to eighty hours. Seven patients were operated on under twelve hours; of these 2 died. In 8 instances the perforation involved the anterior wall of the stomach; in 6 of these it was toward the lesser curvature and close to the pylorus. In 2, the posterior wall was the seat; in 1 of these about its center, and in the other at the pylorus. In the 3 duodenal cases the ulcer was situated in the anterior wall of the first part, so that it might be said that in 11 out of the 13 cases the ulcer was situated in the immediate neighborhood of the pylorus.

20 *Ra[illegible] Maldevelopment. B. N. Ghost.

20. **Congenital Maldevelopment.**—The points noted in this case by Ghost were: 1. Talipes of the right foot; besides there were six toes on that foot. 2. Imperforate anus. 3. No external organs of generation, but only an atrophied scrotum, without the testes in it. 4. The abdominal wall, from the navel downward in the middle line, was partly deficient, and there was a protrusion, possibly the lower gut, with an opening at the end, looking upward, and through which the child passed stools. This protrusion could not be separated from the wall with which it was intimately fixed. The navel coalesced with this protruding mass, the umbilical cord coming out from the top. 5. Urine was passed in drops from a very small opening just under the protruding mass, but there was nothing like a urethra. The child was otherwise healthy and took milk well. No other organs seem to have shared in the defective growth. Heart sounds were normal. The whole protruded portion was not covered with skin, but had a mucous lining, quite soft and red.

Ghost believes that the rectum had no mesorectum developed to keep it *in situ;* it turned upward and found its way through the abdominal wall, which was deficient, and got fixed there. The opening at the end of it, which still serves as the outlet for stools, is looking upward and is big enough to admit a goose-quill. There being no external organs of generation and no urethra, the neck of the bladder opened directly at the lower part of the deficient wall.

27 *Abdominal Crises in Diabetes. R. M. Downes and R. A. O'Brien.

27. **Abdominal Crisis in Diabetes.**—Downes and O'Brien report two cases which suggest that a condition resembling abdominal crisis, apparently requiring operation, may occur in diabetes. They claim that a routine test for sugar in the urine in all acute surgical abdominal cases is not sufficient, for diacetic acid and acetone may be present in the absence of sugar in the urine. The first case was at first regarded as one of acute intestinal obstruction. The patient complained of pain in the lower abdomen, extending right across, and this pain had apparently gradually increased in severity. Bowels had not been open for about thirty-six hours—not even to flatus. Vomiting occurred three or four times during the day, and about two hours before admission the patient became very restless, with a rather vacant expression, and his mental condition became progressively duller, so that he was only semi-conscious on admission, and quite unable to answer any questions rationally. It was known that he had suffered from diabetes mellitus for the past eighteen months.

When about to operate it was found that one drop of urine markedly reduced Fehling's solution, and that the test with ferric chlorid for aceto-acetic acid was positive, so that it was considered wiser not to operate. The patient was sent back to the ward and given rectal injections of sodium bicarbonate solution every four hours. His bowels were slightly open a few hours later. He was given sodium bicarbonate—an ounce to a pint—intravenously, also rectal injections of half a pint, containing sodium bicarbonate (half an ounce) with dextrose (a dram) every four hours. He had two hourly drinks containing sodium bicarbonate half an ounce. At first his condition improved, but later the coma increased, and he died the next morning. At the post-mortem examination nothing abnormal was found in the gastrointestinal tract; the pancreas was small, atrophic and firm, but no microscopic examination was made; the kidneys were rather large, no other pathologic conditions being apparent. A younger brother, also a diabetic, died with rather similar symptoms.

The second patient, a girl, had been on strict diet for two months, with entire disappearance of sugar. Limited carbohydrate (toast) added to the diet, caused immediate reappearance of sugar (1.25 to 2.25 per cent., acid 1030, 21 to 40 ounces per day). Milk and toast were withheld, and the sugar immediately disappeared. Finally the patient vomited several times, and looked ill, complaining of intermittent paroxysms of abdominal pain. A late afternoon specimen of urine contained some diacetic acid and a slight trace of acetone. She was given a high enema, with return of a fair quantity of feces. Late that evening she complained of severe pain over the right kidney, traveling toward the labia. Early the following morning there was constant vomiting, with pulse 140, temperature 99.4 F. General tenderness over abdomen, dulness to deep and light percussion over lower abdomen, below a line joining the anterior superior spines, convex upward, and passing through the umbilicus, resonant in flanks, slight distention of upper abdomen, and greatly decreased liver dulness, no rigidity or lessened respiratory movement. Leucocytes, 47,000 and 50,000 (two counts). Some diacetic acid and acetone were present. A diagnosis was made of acute intestinal obstruction of some undetermined kind, probably causing autointoxication with production of diacetic acid and acetone. Later the abnormal abdominal dulness entirely disappeared. In the intervals of pain she was very sleepy, and almost semi-comatose.

It was decided that the child had had an abdominal crisis of unexplained origin, occurring in a diabetic, and, as only 2 drams of sodium bicarbonate out of 6 given by rectum during the morning had been retained, one pint of normal saline, with one dram of sodium bicarbonate were directed into the median basilic vein in forty-five minutes. Marked improvement in color and a drop in pulse rate to 144 was noticed within ten minutes of the insertion of the cannula. Vomiting ceased immediately. The first urine passed was strongly acid. She took 2 ounces of sodium bicarbonate in milk during the next eighteen hours, after which the urine became alkaline, diacetic acid and acetone gradually lessening, disappearing in a period of ten days, though sugar reappeared on a relaxed diet. Further course was uneventful.

35. Vaccination Against Tuberculosis.—Vallée reports what he thinks were the first attempts to hyperimmunize the horse by means of living tubercle bacilli, human or bovine. Of the 11 horses injected in the course of five years, 3 died accidentally and 4 were slaughtered, but not a trace of tuberculosis could be detected in any, while the serum of all had evidently acquired limited specific qualities, adapting it for human vaccination. About 100 tuberculous patients have been vaccinated with the horse immune serum thus obtained, with no mishaps, the results encouraging its further use.

41. Blunders of Diagnosis from Intestinal Worms.—In the first case reported, a young man, a plasterer, had a tendency to mild epilepsy in early childhood but had outgrown it. He applied for relief from symptoms suggesting a serious heart affection, chills, cough, dyspnea, epistaxis, pulse very slow, slight fever, and abnormal heart sounds. Revulsion was applied to the heart region, and strophanthus and calomel were given, but the dyspnea increased with extreme oppression, staccato respiration, pulse of 43 and subnormal temperature; the face flushed and paled alternately. An enema brought a large ascaris and after a course of santonin all symptoms vanished. In the other case, the stools of a little girl, during a gastroenteritis, contained numbers of ovoid vesicles, supposed to be the ova of some unknown helminth until the microscope revealed that they were orange pulp cells.

44. Benefit from Secondary Infection in Tuberculous Processes.—The young man in the case reported presented symptoms of tuberculous purulent pleurisy of acute onset but becoming torpid with encysted pneumothorax. The effusion was evacuated occasionally and signs of secondary infection with the *Staphylococcus aureus* were discovered in a few months. This transformed the torpid tuberculous process and a cure followed. The secondary infection in this case evidently attracted increased numbers of polynuclears and their active ferment dissolved the tuberculous masses and permitted their absorption. After this digestion by the ferment, the tubercle bacilli in the focus were overcome by the natural defenses of the body.

49 Treatment of Varices by "Intramuscular Inclusion of the Veins." M. Katzenstein.

47. Protrusion in Supraclavicular Fossa as Sign of Plethora.—Trunecek calls attention to the marked protrusion of the supraclavicular fossa when the vascular system contains an excessive amount of blood. This plethora is not so evident in the stronger-walled arteries as in the veins, and it is most evident where the veins are large and especially in the supraclavicular fossa. As the veins here dilate, the pressure from the excessive distention elsewhere on the parenchymatous organs is correspondingly reduced. There is no protrusion at this point when there is merely engorgement of blood in part of the vascular system; it appears only when the plethora is general, and generally is a sign that venesection is required. When sufficient blood has been withdrawn the protrusion subsides.

56 Alcohol and Iodin Disinfection of Hands and Field of Operation. (Desinfection der Hände und des Operationsfeldes mit Alkohol und Jodtinctur.) I. I. Grekow.

51. Treatment of Spondylitic Paralysis.—Gaugele declares that slow gradual reduction of the hump has proved extremely effectual in his experience in the cure of paralysis resulting from the deformity. He applies the correcting force after the child has been encased in a plaster cast reaching from the buttocks to the chin. The force is applied by means of a perpendicular screw in the top of a right-angled frame screwed to the table on which the child lies. A metal plate, cushioned with felt, is interposed between the hump and the correcting screw and the child rests on two concave cross-bars but does not feel them through the plaster cast. Gaugele has applied the correction 140 times in thirty cases, and has had a mishap in only one instance—a boy of 13 experienced transient tenesmus and weakness of the legs, but this was before the present dosage of the force had been adopted. He relates the details of a number of the cases in which complete paralysis or paresis was entirely cured by this simple technic which allows the children to be up and about, besides other advantages. The two cases of which illustrations are given show excellent results; the hump had existed for four and six years.

52. Treatment of Deformities.—Krukenberg thinks that sufficient attention is not paid to weight-bearing as a factor in the aggravation of commencing deformities. If a post stands squarely on top of another post of the same diameter, pressure from above will hold the posts all the more securely, but if the top of the lower post is pushed out of plumb, pressure from above only aids in pushing the lower post farther out of the perpendicular, and the lower end of the upper post follows until the juxtaposed ends form an angle instead of a straight line. If the bottom of the lower post can then be tilted in such a way as to bring the plumb-line still through the center of the juxtaposed ends of the posts, pressure from above will still hold them together and tend to correct the position back into the single vertical line. This is the principle which he applies in correction of genu valgum and genu varum and other deformities, and with which he has obtained good functional results. Uncorrected, the deformity is being constantly aggravated by the weight-bearing pressure. He gives mathematical diagrams to explain the principle more fully and to show its application to various deformities. For flatfoot, a stirrup-like projection from the sole of the shoe, between the heads of the metatarsal bones and the tuberosity of the calcaneus, prevents the foot from being planted with the weight in the center; the weight has to be thrown either on the toes or on the heel, each of which positions corrects the tendency to flatfoot and puts an end to the flatfoot disturbances. Thirty-two illustrations accompany the article, showing the application of functional correction in this way to various deformities.

53. **Rectal Cancer.**—Zinner reports the ultimate outcome of 320 cases of rectal cancer in which an operation was done at Hochenegg's clinic since 1887. Permanent cures were realized in 25 per cent. of the 256 cases with an interval of more than three years. He gives summaries of 201 cases. His experience indicates that a complete cure is possible with any form of epithelial cancer, so that the anatomic variety is of comparatively little moment in comparison to the clinical course.

54. **Operative Treatment of Gastric Ulcer.**—Payr has treated gastric ulcer with resection or excision in seventeen cases since 1902, and states that the indications must be strictly individualized for each case but, other things being equal, that resection guarantees better results than excision. He urges the necessity for keeping record of the after-history of such patients to determine the technic ensuring the most favorable end-results, and whether resection and excision promise results superior to gastroenterostomy enough to justify their more common use.

55. **Trephining After Traumatic Injury of the Vault of the Skull.**—One of the eleven patients whose cases are reported by Kusnetzow was a woman of 70; the others were men. Each had a compound fracture of the vault of the cranium. When splinters are driven inward, the earlier the operative intervention the better the results; with simple fracture it is not indicated unless there are brain symptoms, and with simple fissure injuries expectant treatment is justified if the patient can be kept under constant supervision. Primary trephining is better for various reasons than when done secondarily. In case meningitis develops, the best treatment is by broad exposure of the field, by removal of large pieces of the skull bones, and introduction of absorbent tampons under the opened dura. When an operation has been done for cranial injury, the patients should be kept under observation for years to note the condition of the central nervous system in after years. Injuries of the frontal lobe are liable to entail a peculiar change in the character and temperament, a tendency to silly joking. *Witzelsucht*, the Germans call it.

62 *Specific Precipitin [illegible] and Influence o [illegible] I K [illegible] Spenglerschen [illegible]

57. **Spengler's I K in Treatment of Pulmonary Tuberculosis.**—Alexander reports indifferent results in the 11 cases in which this treatment was systematically applied. It proved by no means so harmless as Spengler claims, a febrile reaction being frequent with minute dosage.

58. **Modifications in the Death-Rate with the Progress of Civilization.**—Köhler cites historical records to show the conditions in regard to public health and hygiene in Germany from the thirteenth century to date. There are no records of the death-rate before that time. The wars and dispersion of troops at the close of campaigns contributed to the spread of epidemics, fully one-fourth of the population of Europe succumbing to the plague in 1347-1350. He states that at the beginning of the thirteenth century there were 19,000 leper asylums. Until the beginning of the fourteenth century there was no such thing as a medical profession, the care of the sick being almost exclusively in the hands of the priests or barbers. But as a medical profession became organized the members early acquired influence and many privileges in the cities, and city physicians were appointed. From this period hygienic conditions began to improve and the death-rate to decline.

60. **Diagnosis of Tuberculosis by Anaphylaxis.**—Roepke was unable to confirm Yamanouchi's statements in regard to the diagnostic value of the anaphylactic reaction in tuberculosis. (His statements were summarized in The Journal, Jan. 9, 1909, page 172.) Roepke is inclined to attribute Yamanouchi's findings to the preservative in the tuberculin used for the tests, as he was able to elicit the anaphylaxis reaction with a carbolic-acid solution alone.

62. **Spengler's I K in Pulmonary Tuberculosis.**—This communication issues from Spengler's laboratory at Davos and the findings in 1,200 examinations of blood mostly from different persons, are presented in tabulated form with the clinical experiences and conclusions in regard to the influence on the "blood-cell immunity" of I K and tuberculin. Eleven tables of curves are given showing the findings in regard to human and bovine tubercle bacilli under the influence of this specific treatment. The conclusions confirm, he asserts, his previous announcements in regard to the red blood corpuscles being the producers and storehouses of the immune bodies. (I K stands for *Immun-Körper*, "immune bodies.")

64 Chlamydozoa in [illegible] Neonatorum. L. Halberstaedter
65 Cobra Venom Te [illegible] ie Ablenkung der Kobragifthämc [illegible] L. Omorokow.

63. **Albuminuria and Tube-Casts with Chronic Constipation.**—Ebstein always found the tube-casts few, small and hyaline when they were due to chronic constipation. In one such case a woman had been referred to him for chronic nephritis with hypertrophy of the heart, but all the symptoms subsided when the existing constipation was relieved, and there have been no signs of nephritis during the ten years since. The grave prognosis in this case had been based on the tube-casts and the fat granules clinging to them and the frequent, intense headache supposed to be a symptom of uremia. The toxins developed in constipation irritate the surface of the tubules in the kidneys, without injury of the parenchyma and interstitial tissue, but whether actual nephritis can develop merely from chronic constipation is still a question. It is certain, however, that in case of actual nephritis or other severe infections every effort must be made to put an end to autointoxication from chronic constipation. For this he has found large oil enemas the most effectual means. In some recent cases of severe diabetes the albuminuria vanished when the constipation was relieved, and even the glycosuria has materially subsided under appropriate diet. In all such cases the prognosis should not be made until the effects of constipation have had time to subside.

67 *Indications and Technic for Puncture of the Pleura. H. Hochhaus.

68 *The Epidemic of Acute Infantile Spinal Paralysis. P. Krause and E. Meinicke.
69 *Seroreaction in Idiots. (Wassermannsche Reaktion bei Idiotie). Kellner, Clemenz, Brückner and Rautenberg.
70 Negative Results of Serotherapy of Pneumonia in Children. (Kinderpneumonie und Pneumokokkenheilserum.) H. Brüning.
71 Negative Results of I K in Treatment of Tuberculosis. O. Roepke, H. Weicker and B. Bandelier.
72 *Objective Index of Condition of Nourishment. (Versuch zur objektiven Darstellung des Ernährungszustandes.) K. Oppenheimer.
73 Placenta Praevia. M. Hirsch.

66. **Indications for Treatment of Contracted Pelvis.**—Veit discusses the various measures in vogue among obstetricians and the indications for them according to the most recent published data and his own experience. He summarizes as follows his views in regard to the indications: Avoid all measures during pregnancy and in prophylaxis. Operate only in strictest necessity. Cesarean section should be done with an absolute contracted pelvis. With moderately contracted pelvis, in case of peril to the mother, forceps may be allowable in a few cases but otherwise Cesarean section is indicated. Pubiotomy is indicated in case of fever and streptococci in the birth passage. Version should be performed in case of peril to the child; Cesarean section only when version or forceps is impossible. All other operative measures should be rejected, as a rule, although they may be occasionally justified in special cases.

67. **Indications and Technic for Puncture of the Pleura.**—In concluding his article Hochhaus mentions that he has applied in a few cases Gilbert's method of autoserotherapy, reinjecting at another point a small amount of the effusion aspirated. The results were not conclusive in his hands but he adds that they have been satisfactory in the experience of others, although not so striking as those realized by Gilbert.

68. See Berlin letter, The Journal, Nov. 6, 1909, page 1575.

69. **Seroreaction in Idiots.**—Kellner states that among 216 idiots tested for syphilis by the Wassermann technic, a positive response was obtained in only 16. Some French writers have recently published a series of 76 positive responses in 246 idiots tested. Kellner thinks that the rarity of positive findings in his series shows that syphilis is not an important direct factor in the etiology of idiocy. Among the 16 giving a positive response to the Stern modification of the Wassermann technic, only 6 were free from signs of inherited or acquired syphilis, while the other 10 were in the group of 16, who were the only known syphilitics among the 800 idiots in the institutions investigated.

72. **Objective Index for the State of Nourishment.**—Oppenheimer says that he has long felt the need of some means to express objectively the actual condition of the patient in regard to nourishment, the significance of the terms "well" and "poorly nourished" varying with each speaker. After years of investigation he announces that the chest measure, taken at the nipples, multiplied by the circumference of the middle of the upper arm and divided by the height, gives a "nourishment measure" which is small in the poorly-nourished and large in the well-nourished and can thus serve as an index for the conditions in this respect. A still more exact index is the quotient of the chest measure divided by the arm measure; this he calls the "nourishment quotient." In a group of 123 well-nourished persons, the "nourishment measure" was 6.6 and the "nourishment quotient" 31.2 in 31 new-born *infants*; 8.5 and 31.4 in 34 older infants; 9.1 and 30.9 in 8 children, and 14.27 and 29.8 in 50 soldiers. In 110 moderately well-nourished infants and children the measure ranged from 5.9 to 9.3 and the quotients from 27.5 to 29.3. In 26 poorly nourished infants and children the measure was 5.6 to 7.1, and the quotient 25.9 to 27.1, while they were respectively 11.7 and 26.2 in 28 adult consumptives. Comparison of extensive series shows that the "nourishment measure" increases with the age but that the "quotient" is independent of the age and is a more exact index of the true relative condition of nourishment. The great drawback of the method is that it cannot be applied to women on account of the development of the breasts, and that a contracted thorax gives measurements liable to be misleading. In the 50 soldiers examined, the nourishment quotient averaged 30, the average chest measure being 92.1 cm. and the arm measure 27:4 cm., with an average height of 176.7 cm.

87 *Stab Wounds of the Liver. (Stichverletzungen der Leber.) A. Nehrkorn.

87. **Stab Wounds of the Liver.**—Nehrkorn operated on three patients with stab wounds of the liver in the course of a few weeks in 1905. The injury was made with a knife *with suicidal intent in one case*, but it soon healed without complications. In another case a boy of 9 was impaled on an iron spike; the wound in the liver soon healed, although a hernia at the point where the drain had been inserted required a second operation three years later. In the third case *a man fell on a tool* he was carrying. The wound in the liver in all these cases was drawn up with two or three sutures. An empyema developed in the third case and a series of complications followed, but with final restoration to comparative health.

99 Measurement of Radium Emanations. (Zur Messung der Emanation.) W. D. Lenkei and E. Weiss.

94. **Venous Thrombosis and Pulmonary Embolism.**—Kretz has been able *to find some primary infectious focus in every* case of fatal pulmonary embolism from primary thrombosis. In some cases the walls of the vein are inflamed but in others infection of the blood is responsible for the intravascular coagulation.

95. **Treatment of Enlargement of the Prostate.**—Wulff calls attention to the fact that sometimes it is impossible to palpate the prostate causing disturbances; in two such cases the gland was even abnormally small, and yet prostatectomy was followed by a clinical cure. Such cases reduce the impor-

tance for examination of the prostate by way of the rectum. The most important means for diagnosis is the discovery by catheterization of residual urine. When there is no trace of this, the disturbance is usually due to neurasthenia or kidney disease. In one such case a man of 70 had pus in the urine and signs of enlargement of the prostate, but the absence of residual urine led to discovery of a tuberculous process in the right kidney. In another case a man of 55 was referred to Wulff for prostatectomy after fifteen years of symptoms; ligation of the vasa deferentia ten years before had failed to benefit. The trouble proved finally to be tabes. In another similar case a man of 50 had complete retention about twice a year but no residual urine and he was advised against an operation. The diagnosis was cleared up by other signs later of a nervous affection. After discovery of residual urine, the nervous system should be examined and the prostate palpated through the rectum to exclude cancer and tuberculosis. Cystoscopy is generally unnecessary. A careful examination should also be made for a calculus; the presence of stones for years in the bladder may cause no symptoms. The bowels must be kept open and regular, to prevent aggravation of prostatic trouble. Extreme care should be taken not to "catch cold," as this is especially liable to induce cystitis. Such patients should sleep in a warm room in winter and should wear woolen stockings and underwear. Wulff deprecates the dread of the catheter. If infection, hemorrhage and debility compel surgical measures, the only treatment is prostatectomy; partial operations are inadvisable.

96. **Headache and Syphilis.**—Pickenbach reports two interesting cases in which tentative syphilitic treatment cleared up the diagnosis and cured intense headache rebellious to all other measures. The first patient was an apparently healthy woman of 38, with a healthy husband and children. Headache suddenly developed refractory to treatment for neuralgia. Examination for a brain tumor proved negative, but an old scar gave the clue to a mild brief syphilitic infection twenty years before, and complete cure followed under potassium iodid. The other patient was a young man.

Monatsschrift für Geburtshülfe und Gynäkologie, Berlin

October, XXX, No. 4, pp. 417-540

100 *Genital Hemorrhages in Hemophiliacs. (Genitalblutungen bei Hämophilie.) L. Fränkel and L. Böhm.
101 Is Cesarean Section an Advance in Treatment of Placenta Prævia? (Bedeutet der Kaiserschnitt einen Fortschritt in der Therapie der Placenta prævia?) J. Novak.

103 Elimination of Antitoxin and Precipitinogen Through the Mammary Gland of Passively Immunized Mothers. (Ausscheidung von Antitoxin und Präzipitinogen durch die Milchdrüse bei passiv immunisierten Müttern.) M. Sohma.

100. **Genital Hemorrhage in Hemophiliacs.**—Fränkel and Böhm review the facts known to date in regard to bleeders; two-thirds of all the hemophiliacs known belong to bleeder families. The majority of the bleeders die young, but Fränkel and Böhm have discovered that this hemorrhagic diathesis is fully as common among women as in the male sex. They have encountered 7 such cases in which nothing but hemophilia could explain the tendency to genital hemorrhage. The hemophilia was evidently inherited in 5 and sporadic in the other cases. They have found records of 151 similar cases in the literature, with a positive heredity in 99 cases, dubious in 18 others. The data show that the genital organs seem to possess some special mode of defense so that even in hemophiliacs the danger from this source is not so excessive as might be expected, although in 10 cases on record the women bled to death during menstruation while 6 others barely escaped this fate. In 32 cases the hemorrhage never ceased spontaneously. The duration of the hemorrhage ranged from three to sixty-four days, in one case over fifteen months. There did not seem to be any special tendency to abortion or premature delivery in these women; 100 became pregnant. There were 30 fatal hemorrhages in the total of 151 cases, but only 24 in consequence of genital hemorrhages. Prophylaxis and treatment comprise internal treatment of the hemorrhagic diathesis and local gynecologic measures; marriage can be permitted to a male hemophiliac but not to a female. Besides general tonic measures, he advises calcium salts internally and, locally, adrenalin, gelatin and blood serum; tamponing of the uterus and vagina is the sovereign measure, gelatin and serum requiring at least two hours before their influence is felt. The general impression left by the article is that although hemophilia is always a serious affection, yet it can be kept under control better in women than in men. Women are naturally used to greater losses of blood than men, and are better provided with means to arrest hemorrhage and to recuperate after loss of blood. It is generally assumed that women are less subject to hemophilia than men, the proportion being stated variously as 1 in 4 down to 1 in 13. The total 104 cases in which female hemophilia was manifested in genital hemorrhage are tabulated for comparison, the list filling twenty pages.

102. **Sterile Catgut.**—The Journal has mentioned from time to time Kuhn's plea that catgut should be obtained and prepared with as strict regard to asepsis at every stage of the process as in the production of diphtheria antitoxin. He here describes the technic which he has worked out from this point of view to produce what he asserts is "absolutely sterile catgut."

109 Alimentary Glycosuria in Chronic Enteritis. K. Funck.
110 *Radiotherapy of Tuberculous Bone Lesions. (Strahlenbehandlung der [illegible] d.
111 Influence of Car[illegible] le. (Fünfter Bericht über [illegible] in Karlsbad auf das Gallensteinleiden.) F. Fink.
112 *Geographical Distribution of Diabetes. B. T. Williamson.

104. **Suture of Lung for Gunshot Wound.**—Grasmann has found on record 18 cases of injury of the lung treated by suture. The list includes 9 cases of gunshot wounds with recovery of 6 of the patients and 6 stab wounds with 5 recoveries, a fatal case of rupture of the lungs, and 2 cases in which the actual injury is not mentioned. He reports the details of 2 cases from his own experience in which prompt suture of the lung after a gunshot wound was followed by recovery. The indication for operative interference in both was the distention from a pneumothorax and extravasation of blood in the pleura. The patients made a smooth recovery in each case, which he attributes to the complete evacuation of all blood from the pleural cavity.

105. **The Seroreaction in Syphilis.**—Reinhart reports application of the Wassermann test in 1,600 cases. The findings were almost invariably negative in cerebral syphilis but positive findings were constant in syphilitic bone lesions. Of the parasyphilitic affections, paralysis gave the highest proportion of regular serum and cerebrospinal fluid positive findings. In tabes the findings were more frequently positive in the early than in the later phases.

107. **Early Diagnosis of Measles.**—Hecker has noticed a marked reduction in the total number of leucocytes as an early sign of measles infection, sometimes fully ten or eleven days before Koplik's spots became evident, but as a rule from one to three days before the development of the spots. There was a reduction also in the numbers of lymphocytes during the incubation of measles, and from three to five days before the spots developed. There seems to be actually a disappearance of lymphocytes with a slight increase in the neutrophiles. This premonitory reduction in the numbers of lymphocytes and the reduction in the total numbers of leucocytes just before the appearance of the eruption may prove important for early differentiation of measles in institutions.

108. **Static Disturbances in the Feet.**—Tausch has had occasion to study in his own person a disturbance in the foot which causes great discomfort with scarcely any objective

findings. The foot is inclined to assume the valgus position when bearing weight and it tires readily. The fatigue is felt more in the calf of the leg than in the foot itself and pain develops similar to that of phlebitis, for which it is often taken. The pain persists even after retiring. It may extend into the thigh or buttocks and may simulate neuralgia. Various muscles become involved as the insufficiency of the muscles of supination increases. Treatment should include the wearing of proper shoes, strengthening the supination muscles with gymnastic exercises, learning to plant and raise the foot normally, supplemented by mechanical means to restore normal static conditions in the foot, correcting the pronation angle and supporting the arch until the foot is brought from the valgus position into supination, placing it on a slanting plane provided by an insole made from a cast of the foot taken while it is bearing the weight of the body. With a correct insole, the stiff joint mobilized with gymnastic exercises, and the atrophied muscles strengthened, all disturbances vanish at once, and the patients are relieved from what seemed to be an incurable and tormenting affection. Tabes had been assumed in some of the cases to which he refers.

110. Radiotherapy of Tuberculous Bone Processes.—Freund discusses the advantages of heliotherapy in treatment of these lesions, supplemented by radium and Roentgen treatment on days without sufficient sunshine. His experience has been favorable.

112. Geographical Distribution of Diabetes.—Williamson's figures show that the mortality from diabetes per 100,000 inhabitants ranges from 6.6 to 12.7 in the different cities of England and Wales, with a general average for the country of 9.6; in Malta and Gozo, 37.8. In Europe the extremes are 5 in Helsingfors, 4.5 in Italy to 15.8 in Copenhagen, 20 in Berlin and 25.8 in Bordeaux; in Asia, from 0.15 in Hong Kong to 9.2 in Calcutta; in America, from 5.8 in the province of Quebec to 27.3 in Worcester, Mass., with 17.4 in New York, 10.7 in Chicago and 17.9 in Boston, and a general average for the United States of 13.9; for Australia of about 8; for Buenos Aires, 5.6, and Cuba 2.8. His research, he states, shows that the disease is gradually increasing. Men are more frequently affected than women in most localities.

114 Granules in Leucocytes in Gonorrhea, Taking Sudan Stain. (Le granulazioni sudanofili dei leucociti nel sangue dei blenorragici.) G. Sarra.

October 19, No. 125, pp. 1321-1328

115 Difference Between the Temperature of the Axillæ in Tuberculous Patients. (Differenze tra le due temperature ascellari nei polmoniti.) L. Casali.

October 21, No. 126, pp. 1330-1336

116 Surgical Treatment of Jacksonian Epilepsy. T. Clemente.

113. Suture of the Ureter.—Boari introduces a catheter into the ureter and merely approximates the stumps of the ureter over the catheter, joining the stumps together with interrupted sutures without invaginating one stump into the other which is almost sure to entail stenosis. The retention of the catheter in the ureter caused no disturbances, although it projected for nearly three inches into the bladder in the case described. After allowing ten days for the suture of the ureter to heal, he extracted the retained catheter with the aid of the cystoscope, and there has been nothing to suggest any anomaly in the ureter during the two years since. A catheter passed through the ureter up into the kidney meets with no obstacles. The ureter was injured in his case during a hysterectomy.

Policlinico, Rome

October 10, XVI, No. 41, pp. 1285-1316

117 *Hemolytic Jaundice and Syphilitic Infection. (Gli itteri emolitici e l'infezione sifilitica.) G. Basile.

118 *Tabes Dorsalis. (Sopra un caso di tabe dorsale.) E. Fenoglietto.

117. Jaundice from Hemolysis: Syphilitic Origin.—Basile refers to the jaundice in which the trouble is evidently the result of extra fragility on the part of the red corpuscles. Autopsy in the few such cases examined post-mortem disclosed that the liver and biliary passages were intact. Syphilitic infection may be responsible for the extra fragility of the corpuscles in some of these cases.

118. Tabes Dorsalis plus Morphin Addiction.—The gastric crises in the case reported were followed by intestinal crises, sometimes brought on by a purgative or enema. The tabes developed in this case as early as five years after primary syphilitic infection, and mercurial treatment seemed to have a favorable influence in reducing the frequency and severity of the crises.

Policlinico, Rome

October, XVI, Surgical Section, No. 10, pp. 429-476

119 Sarcoma as Recurrence of Carcinoma in the Thyroid. F. Nassetti.

120 *Organic Free Bodies in Hernial Sac and in Peritoneal Cavity. (Dei corpi organizzati nei sacchi erniari e nella cavita peritoneale.) G. Palazzo.

120. Organic Free Bodies in Hernial Sac and Peritoneum.—Palazzo gives the details in tabulated form of 18 cases from the literature in which an organic body was found free in a hernial sac, and of 31 others in which a similar organic body was found free in the peritoneum. In 2 cases personally observed the organic body found non-adherent in the hernial sac was a fragment of omentum, evidently detached from a fold of the omentum included in the hernia at first. He further describes experiments on dogs and guinea-pigs striving to induce the production of an organic foreign body in the peritoneum by injection of fresh fibrin or extract of organs with an internal secretion, or of dead micro-organisms liable to induce precipitation of fibrin. The results were constantly negative.

123 Mixed Cirrhosis. (Contributo clinico ed anatomo-pathologico allo studio delle cirrosi miste.) T. Casoni.

122. Differentiation of Typhoid, Paratyphoid and Malta Fevers.—Rummo tabulates for comparison the various clinical features of these fevers. In the last two the spleen does not become enlarged, or only slightly, late in the disease, while there is generally obstinate constipation and the fever starts with abrupt onset and a chill, without prodrome, while the type is altogether different from the typhoid curve. He warns, however, that in all three the prognosis should be guarded. The general idea that paratyphoid and Malta fever are benign affections is frequently shown to be erroneous by the serious form which they sometimes assume. In Malta fever in particular, the disease may drag along to such an extent that it may be regarded as the one of the trio which is liable to try the patience most of both patient and physician. Early differentiation of typhoid is of the greatest importance as otherwise household remedies may be applied which are liable to do irreparable harm. The diet may be a little less exclusive in paratyphoid and Malta fever than in typhoid, but he warns that convalescence from typhoid is like a new disease which has to be supervised and combated, mainly on account of the impatience and appetite of the patient and the heedlessness of his friends. Nothing but milk should be allowed, he declares, for a week after defervescence.

tance for examination of the prostate by way of the rectum. The most important means for diagnosis is the discovery by catheterization of residual urine. When there is no trace of this, the disturbance is usually due to neurasthenia or kidney disease. In one such case a man of 70 had pus in the urine and signs of enlargement of the prostate, but the absence of residual urine led to discovery of a tuberculous process in the right kidney. In another case a man of 55 was referred to Wulff for prostatectomy after fifteen years of symptoms; ligation of the vasa deferentia ten years before had failed to benefit. The trouble proved finally to be tabes. In another similar case a man of 50 had complete retention about twice a year but no residual urine and he was advised against an operation. The diagnosis was cleared up by other signs later of a nervous affection. After discovery of residual urine, the nervous system should be examined and the prostate palpated through the rectum to exclude cancer and tuberculosis. Cystoscopy is generally unnecessary. A careful examination should also be made for a calculus; the presence of stones for years in the bladder may cause no symptoms. The bowels must be kept open and regular, to prevent aggravation of prostatic trouble. Extreme care should be taken not to "catch cold," as this is especially liable to induce cystitis. Such patients should sleep in a warm room in winter and should wear woolen stockings and underwear. Wulff deprecates the dread of the catheter. If infection, hemorrhage and debility compel surgical measures, the only treatment is prostatectomy; partial operations are inadvisable.

96. **Headache and Syphilis.**—Pickenbach reports two interesting cases in which tentative syphilitic treatment cleared up the diagnosis and cured intense headache rebellious to all other measures. The first patient was an apparently healthy woman of 38, with a healthy husband and children. Headache suddenly developed refractory to treatment for neuralgia. Examination for a brain tumor proved negative, but an old scar gave the clue to a mild brief syphilitic infection twenty years before, and complete cure followed under potassium iodid. The other patient was a young man.

Monatsschrift für Geburtshülfe und Gynäkologie, Berlin

October, XXX, No. 4, pp. 417-540

100 *Genital Hemorrhages in Hemophiliacs. (Genitalblutungen bei Hämophilie.) L. Fränkel and L. Böhm.
101 Is Cesarean Section an Advance in Treatment of Placenta Prævia? (Bedeutet der Kaiserschnitt einen Fortschritt in der Therapie der Placenta prævia?) J. Novak.
102 *Sterile Catgut. (Steril-Katgut.) F. Kuhn (Kassel).
103 Elimination of Antitoxin and Precipitinogen Through the Mammary Gland of Passively Immunized Mothers. (Ausscheidung von Antitoxin und Präzipitinogen durch die Milchdrüse bei passiv immunisierten Müttern.) M. Sohma.

100. **Genital Hemorrhage in Hemophiliacs.**—Fränkel and Böhm review the facts known to date in regard to bleeders; two-thirds of all the hemophiliacs known belong to bleeder families. The majority of the bleeders die young, but Fränkel and Böhm have discovered that this hemorrhagic diathesis is fully as common among women as in the male sex. They have encountered 7 such cases in which nothing but hemophilia could explain the tendency to genital hemorrhage. The hemophilia was evidently inherited in 5 and sporadic in the other cases. They have found records of 151 similar cases in the literature, with a positive heredity in 99 cases, dubious in 18 others. The data show that the genital organs seem to possess some special mode of defense so that even in hemophiliacs the danger from this source is not so excessive as might be expected, although in 10 cases on record the women bled to death during menstruation while 6 others barely escaped this fate. In 32 cases the hemorrhage never ceased spontaneously. The duration of the hemorrhage ranged from three to sixty-four days, in one case over fifteen months. There did not seem to be any special tendency to abortion or premature delivery in these women; 100 became pregnant. There were 30 fatal hemorrhages in the total of 151 cases, but only 24 in consequence of genital hemorrhages. Prophylaxis and treatment comprise internal treatment of the hemorrhagic diathesis and local gynecologic measures; marriage can be permitted to a male hemophiliac but not to a female. Besides general tonic measures, he advises calcium salts internally and, locally, adrenalin, gelatin and blood serum; tamponing of the uterus and vagina is the sovereign measure, gelatin and serum requiring at least two hours before their influence is felt. The general impression left by the article is that although hemophilia is always a serious affection, yet it can be kept under control better in women than in men. Women are naturally used to greater losses of blood than men, and are better provided with means to arrest hemorrhage and to recuperate after loss of blood. It is generally assumed that women are less subject to hemophilia than men, the proportion being stated variously as 1 in 4 down to 1 in 13. The total 104 cases in which female hemophilia was manifested in genital hemorrhage are tabulated for comparison, the list filling twenty pages.

102. **Sterile Catgut.**—The Journal has mentioned from time to time Kuhn's plea that catgut should be obtained and prepared with as strict regard to asepsis at every stage of the process as in the production of diphtheria antitoxin. He here describes the technic which he has worked out from this point of view to produce what he asserts is "absolutely sterile catgut."

Münchener medizinische Wochenschrift

October 12, LVI, No. 41, pp. 2089-2144

104 *Suture of Gunshot Wounds of the Lung. (Behandlung schwerer Schussverletzungen der Lunge mit Naht.) M. Grasmann.
105 *Serodiagnosis of Syphilis. (Erfahrungen mit der Wasser- llsreaktion.) A. Reinhart.
der Lues.) H. Liefmann.
106 Co sane. (Die Muchsche Hemmungsreaktion bei Geisteskranken.) Nitsche, H. Schlimpert and H. Dunzelt.
107 *Early Diagnosis of Measles. (Zur Frühdiagnose der Masern.) Hecker.
108 *Disturbances in the Feet. (Fussbeschwerden.) F. Tausch.
109 Alimentary Glycosuria in Chronic Enteritis. K. Funck.
110 *Radiotherapy of Tuberculous Bone Lesions. (Strahlenbehandlung der Knochentuberkulose.) L. Freund.
111 Influence of Carlsbad Cure on Gall-Stone Trouble. (Fünfter Bericht über den Einfluss des Kurgebrauches in Karlsbad auf das Gallensteinleiden.) F. Fink.
112 *Geographical Distribution of Diabetes. B. T. Williamson.

104. **Suture of Lung for Gunshot Wound.**—Grasmann has found on record 18 cases of injury of the lung treated by suture. The list includes 9 cases of gunshot wounds with recovery of 6 of the patients and 6 stab wounds with 5 recoveries, a fatal case of rupture of the lungs, and 2 cases in which the actual injury is not mentioned. He reports the details of 2 cases from his own experience in which prompt suture of the lung after a gunshot wound was followed by recovery. The indication for operative interference in both was the distention from a pneumothorax and extravasation of blood in the pleura. The patients made a smooth recovery in each case, which he attributes to the complete evacuation of all blood from the pleural cavity.

105. **The Seroreaction in Syphilis.**—Reinhart reports application of the Wassermann test in 1,600 cases. The findings were almost invariably negative in cerebral syphilis but positive findings were constant in syphilitic bone lesions. Of the parasyphilitic affections, paralysis gave the highest proportion of regular serum and cerebrospinal fluid positive findings. In tabes the findings were more frequently positive in the early than in the later phases.

107. **Early Diagnosis of Measles.**—Hecker has noticed a marked reduction in the total number of leucocytes as an early sign of measles infection, sometimes fully ten or eleven days before Koplik's spots became evident, but as a rule from one to three days before the development of the spots. There was a reduction also in the numbers of lymphocytes during the incubation of measles, and from three to five days before the spots developed. There seems to be actually a disappearance of lymphocytes with a slight increase in the neutrophiles. This premonitory reduction in the numbers of lymphocytes and the reduction in the total numbers of leucocytes just before the appearance of the eruption may prove important for early differentiation of measles in institutions.

108. **Static Disturbances in the Feet.**—Tausch has had occasion to study in his own person a disturbance in the foot which causes great discomfort with scarcely any objective

findings. The foot is inclined to assume the valgus position when bearing weight and it tires readily. The fatigue is felt more in the calf of the leg than in the foot itself and pain develops similar to that of phlebitis, for which it is often taken. The pain persists even after retiring. It may extend into the thigh or buttocks and may simulate neuralgia. Various muscles become involved as the insufficiency of the muscles of supination increases. Treatment should include the wearing of proper shoes, strengthening the supination muscles with gymnastic exercises, learning to plant and raise the foot normally, supplemented by mechanical means to restore normal static conditions in the foot, correcting the pronation angle and supporting the arch until the foot is brought from the valgus position into supination, placing it on a slanting plane provided by an insole made from a cast of the foot taken while it is bearing the weight of the body. With a correct insole, the stiff joint mobilized with gymnastic exercises, and the atrophied muscles strengthened, all disturbances vanish at once, and the patients are relieved from what seemed to be an incurable and tormenting affection. Tabes had been assumed in some of the cases to which he refers.

110. Radiotherapy of Tuberculous Bone Processes.—Freund discusses the advantages of heliotherapy in treatment of these lesions, supplemented by radium and Roentgen treatment on days without sufficient sunshine. His experience has been favorable.

112. Geographical Distribution of Diabetes.—Williamson's figures show that the mortality from diabetes per 100,000 inhabitants ranges from 6.6 to 12.7 in the different cities of England and Wales, with a general average for the country of 9.6; in Malta and Gozo, 37.8. In Europe the extremes are 5 in Helsingfors, 4.5 in Italy to 15.8 in Copenhagen, 20 in Berlin and 25.8 in Bordeaux; in Asia, from 0.15 in Hong Kong to 9.2 in Calcutta; in America, from 5.8 in the province of Quebec to 27.3 in Worcester, Mass., with 17.4 in New York, 10.7 in Chicago and 17.9 in Boston, and a general average for the United States of 13.9; for Australia of about 8; for Buenos Aires, 5.6, and Cuba 2.8. His research, he states, shows that the disease is gradually increasing. Men are more frequently affected than women in most localities.

October 14, XXX, No. 123, pp. 1297-1304

113 *Suture Through Laparotomy of Severed Ureter over Retention Catheter. (Sutura per via addominale dell' uretere sinistro sopra catetere permanente dal rene in vescica.) A. Boari.

October 17, No. 124, pp. 1305-1320

114 Granules in Leucocytes in Gonorrhea, Taking Sudan Stain. (Le granulazioni sudanofili dei leucociti nel sangue dei blenorragici.) G. Sarra.

October 19, No. 125, pp. 1321-1328

115 Difference Between the Temperature of the Axillæ in Tuberculous Patients. (Differenze tra le due temperature ascellari nei polmoniti.) L. Casali.

October 21, No. 126, pp. 1330-1336

116 Surgical Treatment of Jacksonian Epilepsy. T. Clemente.

113. Suture of the Ureter.—Boari introduces a catheter into the ureter and merely approximates the stumps of the ureter over the catheter, joining the stumps together with interrupted sutures without invaginating one stump into the other which is almost sure to entail stenosis. The retention of the catheter in the ureter caused no disturbances, although it projected for nearly three inches into the bladder in the case described. After allowing ten days for the suture of the ureter to heal, he extracted the retained catheter with the aid of the cystoscope, and there has been nothing to suggest any anomaly in the ureter during the two years since. A catheter passed through the ureter up into the kidney meets with no obstacles. The ureter was injured in his case during a hysterectomy.

Policlinico, Rome

October 10, XVI, No. 41, pp. 1285-1316

117 *Hemolytic Jaundice and Syphilitic Infection. (Gli itteri emolitici e l'infezione sifilitica.) G. Basile.

118 *Tabes Dorsalis. (Sopra un caso di tabe dorsale.) E. Fenoglietto.

117. Jaundice from Hemolysis: Syphilitic Origin.—Basile refers to the jaundice in which the trouble is evidently the result of extra fragility on the part of the red corpuscles. Autopsy in the few such cases examined post-mortem disclosed that the liver and biliary passages were intact. Syphilitic infection may be responsible for the extra fragility of the corpuscles in some of these cases.

118. Tabes Dorsalis plus Morphin Addiction.—The gastric crises in the case reported were followed by intestinal crises, sometimes brought on by a purgative or enema. The tabes developed in this case as early as five years after primary syphilitic infection, and mercurial treatment seemed to have a favorable influence in reducing the frequency and severity of the crises.

Policlinico, Rome

October, XVI, Surgical Section, No. 10, pp. 429-476

119 Sarcoma as Recurrence of Carcinoma in the Thyroid. F. Nassetti.

120 *Organic Free Bodies in Hernial Sac and in Peritoneal Cavity. (Dei corpi organizzati nei sacchi erniari e nella cavita peritoneale.) G. Palazzo.

120. Organic Free Bodies in Hernial Sac and Peritoneum.—Palazzo gives the details in tabulated form of 18 cases from the literature in which an organic body was found free in a hernial sac, and of 31 others in which a similar organic body was found free in the peritoneum. In 2 cases personally observed the organic body found non-adherent in the hernial sac was a fragment of omentum, evidently detached from a fold of the omentum included in the hernia at first. He further describes experiments on dogs and guinea-pigs striving to induce the production of an organic foreign body in the peritoneum by injection of fresh fibrin or extract of organs with an internal secretion, or of dead micro-organisms liable to induce precipitation of fibrin. The results were constantly negative.

Riforma Medica, Naples

121 Central Neuropathies of Malarial Origin. (Anartria, convulsioni epilettiformi, sindrome cerebellare.) E. Grande.

October 18, No. 42, pp. 1149-1176

122 *Differentiation, Prophylaxis and Treatment of Septicemic Fevers. (Sulle febbri e febbricole setticemiche polimorfe. XI.) G. Rummo. Commenced in No. 41.

123 Mixed Cirrhosis. (Contributo clinico ed anatomo-pathologico allo studio delle cirrosi miste.) T. Casoni.

122. Differentiation of Typhoid, Paratyphoid and Malta Fevers.—Rummo tabulates for comparison the various clinical features of these fevers. In the last two the spleen does not become enlarged, or only slightly, late in the disease, while there is generally obstinate constipation and the fever starts with abrupt onset and a chill, without prodrome, while the type is altogether different from the typhoid curve. He warns, however, that in all three the prognosis should be guarded. The general idea that paratyphoid and Malta fever are benign affections is frequently shown to be erroneous by the serious form which they sometimes assume. In Malta fever in particular, the disease may drag along to such an extent that it may be regarded as the one of the trio which is liable to try the patience most of both patient and physician. Early differentiation of typhoid is of the greatest importance as otherwise household remedies may be applied which are liable to do irreparable harm. The diet may be a little less exclusive in paratyphoid and Malta fever than in typhoid, but he warns that convalescence from typhoid is like a new disease which has to be supervised and combated, mainly on account of the impatience and appetite of the patient and the heedlessness of his friends. Nothing but milk should be allowed, he declares, for a week after defervescence.

Hospitalstidende, Copenhagen

128 *"Primary" Tuberculosis of the Spleen. (Milttuberkulose.) C. Permin.

124. **Roentgen-Ray Treatment of Skin Diseases.**—Reyn reports from the Finsen Light Institute at Copenhagen the experiences with various skin affections treated by Roentgen exposures during the last year. His experience with eczema was extremely favorable, only 17 of the total of 184 patients not displaying more or less marked benefit, amounting to a permanent cure in 88 and in 15 others after a slight recurrence had been treated. The others did not continue the exposures to a complete cure but were satisfied with the results already attained. He regards Roentgen treatment as the most valuable means at our command for eczema rebellious to the ordinary measures perseveringly applied. The affection in some of his cases was from two to five years' standing in 43, from five to ten in 41, and from ten to twenty in 40. The experiences with other cutaneous affections were contradictory, complete cure in some and failure in others. In treatment he uses only from one-half to two-thirds of the S N erythem dose (Sabouraud and Noire radiometer) and fractions it over three days. The series is repeated again if necessary after a pause of three weeks. In 100 cases of epithelioma the results of Roentgen treatment were also encouraging; much larger doses were required, about two erythem doses, S N, fractioned over two days. He appends an extensive bibliography on Roentgen treatment of cutaneous affections.

128. **Primary Tuberculosis of the Spleen.**—Permin's patient was a man of 21 supposedly healthy until a period of languor and depression so extreme that he entered the hospital after two months. During the last week he had also experienced oppression and pain in the left side of the abdomen, soon accompanied by high fever, slight cyanosis, enlarged glands in the neck, axillæ and groins, a solid tumor in the region of the spleen and anemia. The leucocyte picture was approximately normal. The spleen was found studded with tuberculous nodules and was removed, after which all symptoms vanished and the patient returned to work. Parmin reviews the other cases of the kind on record, this being the eleventh in which splenectomy has been done for primary tuberculosis of the spleen, and discusses the differentiating points. At the time of the operation there were no signs of tuberculosis elsewhere but the patient returned to the hospital before the year was out with pleurisy and signs of apical involvement, although the sputum was free from tubercle bacilli. The glands in the neck suppurated, and after their removal pleurisy developed, which ended fatally on the ninth day. The case emphasizes the importance of general measures after the splenectomy to tone up the general health instead of allowing the patient to resume at once his former occupation. It also shows that splenectomy is a comparatively harmless means of freeing the patient from the otherwise fatal tuberculous process in the spleen.

Ugeskrift for Læger, Copenhagen

September 23, LXXI, No. 38, pp. 1049-1070

129 *Origin of Uric Acid. (Fortsatte Undersøgelser over Urinsyrens Oprindelse.) H. Trautner. Commenced in No. 37.

129. **Origin of Uric Acid.**—Trautner reports extensive research which has convinced him that uric acid is the result of proliferation of colon bacilli causing a more or less latent chronic colitis. These bacilli produce reducing substances which undergo chemical changes in the blood and may be the first stages of uric acid. He discusses the medical history of uric acid, the lack of it in young children, of whom he examined 88, and also the lack of colon bacilli in the new-born and in older infants in health. He found both colon bacilli and uric acid in children with intestinal derangement. In examining 25 older children, including 13 with diarrhea, the presence and amount of uric acid in the urine and of colon bacilli in the feces constantly paralleled each other. He also found in experiments on 22 young rabbits that there was no appreciable uric acid in the urine when there were no colon bacilli in the feces, but that the uric acid appeared when the animals were given colon bacilli added to their food. He also examined 32 typhoid patients, 70 patients who had a history of typhoid, and 327 other persons either normal or with other affections. The uric acid disappears from the urine during typhoid more or less completely and the proportion persists low for a long time, suggesting that the typhoid bacilli seem to deprive the colon bacilli of some substance, normally present in the intestines, which they require for their growth. The proportion of uric acid in the urine of a person with a tendency to gout, rheumatism or uricacidemia increases during constipation He found that the fetal uric acid in the new-born disappeared in the course of five days, and that none was detectable thereafter, while there were no colon bacilli at first and they were scanty in the infants' stools later.

Address

SOME OF THE RELATIONS OF OCCUPATIONS TO MEDICINE *

DAVID L. EDSALL, M.D.
PHILADELPHIA

On an occasion which, as I comprehend it, serves not only as your annual meeting, but also, to a considerable extent, as a means of formally introducing your body to the school of medicine recently inaugurated in this state, it is interesting to reflect that a generation ago conditions were such that the influence exerted on the profession at large by any individual medical school in this country was exercised chiefly through the clinicians connected with the school; while, at present, circumstances are so largely altered that a school like that situated here may have no dealings with the directly clinical side of medicine and yet, youthful as it is, be generally recognized as certain to have a large influence on medical progress, because of the character of the provision it makes for the teaching of the medical sciences. Indeed, the change has been so great that we now hear more frequently and more insistently than ever before the warning that has been uttered at times throughout several generations—among others, by such wise and charming writers as John Brown and Oliver Wendell Holmes—the warning, that is, that we are in danger of overdoing the scientific side of medical instruction at the expense of the clinical. I do not intend to discuss medical education here, or even that constantly recurring question as to the relative amount of time that may properly be assigned to the clinical branches and the medical sciences; but, since it bears closely on my purpose in discussing occupations in their relation to medicine, I would say that I do not feel the slightest sympathy with the frequently expressed fear that the tendency at present is to train up investigators, rather than clinicians, my reason being the very definite one that, to my mind, a sound clinician is essentially an investigator, whether he works in a laboratory with all possible facilities or in hard country practice; whether he conducts extensive studies of special questions or simply attempts to learn as precisely as possible what needs to be done for each separate patient. In the latter case, as much as in any other, he will be successful and useful in direct proportion to the degree to which he has been trained into the point of view and the methods of a careful investigator.

The most apparent defect in medical teaching, it appears to me, is not that students are taught too largely of the medical sciences: it is rather that they are not yet sufficiently trained in making their more scientific information a living and integral part of their clinical procedures, and still tend to place the two in their minds on each side of a wide chasm that is crossed only by means of bridges so frail and slippery that they are all too seldom used. This is not due solely to the methods employed by those who teach the medical sciences; it is equally and perhaps even more largely due to the tendency of those of us who are clinicians to allow both ourselves and our students, in considering clinical questions, to wander more widely into mere impressions and crude hypotheses than we should permit ourselves to do in dealing with matters that relate directly to the medical sciences. This attitude, so common among clinicians, is, I think, in large part due to our misfortune in having been brought up to the almost religious belief that the practice of medicine is an art, rather than a precise science, and an almost purely empirical art at that—a partial truth that, happily, is continually growing less true, but that has done much to obstruct progress, because we can so readily fall back on it, when we feel inclined to be easy-going, rather than precise.

In large part, also, the relative lack of precision in clinical work, a lack that is seen especially in therapeutic practice, is due, not to the impossibility of being exact, but to the fact that it is somewhat difficult to use precise methods in the circumstances of practice, which are so much less favorable to such methods than are the surroundings of the medical sciences. It is, however, largely because it so strikingly illustrates the fact that precise methods tinctured with some personal investigativeness are open to us all even in the most commonplace things in practice to a much larger extent than we customarily make use of them, that a study of occupations in their relation to medicine appears to me to be a matter of most especial interest as an example of the practical value of a training in the preliminary subjects in medicine such as that offered now by your own state school; for, in the consideration of occupations in their relation to disease, and in appreciating their effects properly, we need to make constant and lively use, not only of our knowledge of the medical sciences, but also of whatever knowledge we may possess of an infinite variety of technical subjects. Indeed, in the course of an ordinary practice any one can in this connection, by means of a little extra precision but with very little extra effort, both gain interesting diversion and varied knowledge by inquiring into this point, and at the same time elicit many facts that are extremely valuable in properly comprehending and in treating cases of all sorts; and these facts are often overlooked entirely by the ordinary routine method of recording the occupation of an individual. This point in the history affords, to my mind, more than does any other, an endlessly varied interest, both humane and scientific, on the one hand, and great practical help, on the other; and yet, in many an instance, very little attention is devoted to it.

---

* Address in Medicine at the Annual Meeting of the Wisconsin State Medical Society, Madison, July 1, 1909.

INEXACTNESS IN CASE RECORDS

We often content ourselves with the mere names of occupations; indeed, we very frequently find in case-records names that not only mean absolutely nothing as to what the individual at hand does when at work, but that are mere general terms, covering a host of different occupations—terms, I mean, such as laborer, mechanic, machinist, mill operative, and the like, which are very common even in the best kept of hospital records, so common that Arlidge,[1] in his work on occupational diseases, stated that hospital records are so inexact on this point as to be practically worthless to one who is studying the effects of occupation on health. Though much information has meanwhile been accumulated, there has been no general change in this regard since Arlidge's book was written. While, therefore, we make a great point of putting down the name of a patient's occupation in his record, this is only too often merely a part of a general dull routine, and is frequently of no more value, so far as diagnosis and treatment are concerned, than the name of the patient himself. To be sure, if the patient says that he is a lead-worker, his whole trouble often becomes illuminated at once; if he is a drayman or works with heavy metals, we see immediately that he is subject to severe physical strain; if he is a sailor, we know that he is exposed to rough weather; if he is in finance, we know that he is likely to have severe nervous strain. There are, of course, a variety of such ways in which our common sense and our casually acquired knowledge make us see at once some of the main ways in which particular occupations may affect people; but it may fairly be said that we have too little system in dealing with this question, and that it is too generally the custom to pass over the occupation and go on into the other details of the history, unless there are some peculiar conditions in the case that suggest an unusual degree of relation to the individual's work or unless the mere name that the patient gives recalls at once some familiar consequences of such employment. This is more especially true of work in internal medicine. In some of the specialties there is a wider and often very alert appreciation of the importance of the occupation.

Indifference to this point is assuredly a very stepmotherly way of treating what is one of the chief factors in producing disease; probably, indeed, the most important of all, not only in interesting and unusual cases, but also in a large proportion of instances of the most every-day and commonplace types of disorders. There is a vast difference in the interest and profit attaching to a record of the occupation, if, on the one hand, one merely records the name of the trade, or, on the other hand, inquires routinely into the exact nature of the work in so far as concerns certain points that are likely to have an especially important bearing on the type of case under consideration. It would be folly to recommend that we elicit all the details of the work in all instances, or that we attempt to carry knowledge of the details of all occupations. Unless one should devote his entire time to acquiring information regarding the endless technical details of the almost innumerable occupations that we meet, it is impossible to conceive of carrying with us knowledge of even a small fraction of these sufficiently complete to make us see at once, when the name of a certain employment is mentioned, that this means a particular kind of physical or nervous strain, an especial exposure to dust or to some poisonous substance, or unusual tax in some other way. The impossibility of this is seen, for instance, in the conditions pertaining to lead-poisoning.

OCCUPATIONS PREDISPOSING TO PLUMBISM

Years ago Layet collected one hundred and eleven occupations in which there was more or less danger of lead-poisoning; and, through clinical experience and reading, I have been able to add a considerable number to this list. The uses to which this metal is put are so nearly endless that new sources of poisoning, previously unheard of, are still occasionally appearing. We cannot hope to remember such a mass of facts about one particular form of occupational poisoning, and we can still less attempt to remember the details and varied kinds of dangers associated with large numbers of occupations. We can, however, adopt some system of attempting to elicit the main elements of importance in relation to a particular case. This, I think, can be most readily done by, first of all, getting the patient to tell us briefly, but as clearly as he can, the main details of his work; and then attempting to follow particularly any suggestion that comes from this or from his type of disorder. In case I am not already familiar with the details of the occupation, I try to learn in different cases, as far as possible, what sorts of substances the patient works with, what position he works in, how heavy his work is, what his hours of work are, whether it is day or night work, the degree of exposure to heat, cold, or wet, and a few similar points; and, especially among well-to-do patients, but also with those of simpler life, I determine, of course, the degree of responsibility and general nerve strain.

I am aware that in mentioning such commonplace matters and insisting on their importance I lay myself open to the caustic criticism that James Mackenzie[2] applied long ago to Friedrich Hoffmann, when he said that there are certain persons who go about talking of well-known things as if they were themselves the discoverers of them. While I do not lay claim to be the discoverer of the importance of such things, I do have the temerity to repeat the statement that there is a vast difference between the results obtained in this way and those that one gets from accepting the mere brief statement of the name of the occupation as it is given in the ordinary history.

I may possibly make it clearer that I am not urging the use of methods that are employed by every one, if I give some illustrations. Some of you may not be familiar with the fact that carriage-painters are very much more subject to lead-poisoning than are house-painters. Stüler found in Vienna that they were from ten to twenty times as subject to lead-poisoning as were house-painters; and the average each year among carriage-painters was nearly three days' illness from lead-poisoning for each man employed. Of the painters whom I have seen in the last five years with lead-poisoning, about half were carriage-painters, while, of course, carriage-painters are only a small fraction of the whole number of painters. If we inquire into the details of their work it is perfectly clear why this should be the case, and we need not have been taught it beforehand to realize that it is likely to be true. Contrary to the well-known conditions under which house-painters work, carriage-painters apply a large number of coats of paint and varnish, polishing between each coat, and thereby enveloping themselves in dust which contains much lead. They also work largely in an enclosed atmosphere, to prevent dust and dirt from being blown on the surface, which must remain smooth. Clearly their opportunities for lead-poisoning are very great, as are their opportunities for acquiring respiratory diseases, tuberculosis and the like, to which they are very subject.

[2] A History of Health and the Art of Preserving It. An Account of All that has been Recommended by Physicians and Philosophers toward the Preservation of Health from the Most Remote Antiquity to the Present Time, Edinburgh, 1758.

Again, we know well that workers in wood are subject to the moderately bad mechanical effects of ordinary sawdust. When we inquire more precisely into this, however, we find that a certain number of workers, most strikingly those engaged in working with boxwood, teak, and sequoia woods, are subject also to the general poisonous effects of alkaloids or other substances contained in these woods, which may have interesting and rather serious general effects, chiefly on the circulation and, still more frequently, a marked local effect on the mucous membranes and the skin—a matter that is of some importance in this country and that has been discussed in an interesting way in relation to conditions in England by Oliver.[3]

SCIATICA IN LOCOMOTIVE ENGINEERS

I know of no better additional example of the necessity of obtaining data regarding the occupation of patients than that mentioned to me by Dr. Latta, head of the Pennsylvania Railroad Relief Service. It was found that an especially large number of cases of right-sided sciatica were being reported in locomotive engineers, and it seemed quite clear that this was due to something peculiar in their work. An exact inquiry into the conditions under which these men worked, so far as they bore on the point, almost at once laid emphasis on the fact that every one had known before, but had given no attention to, namely, that the engineman had customarily sat sidewise on the bench of the right-hand side of the engine-cab, and, in the constant jolting, the weight of his body was continually thrown violently on the right thigh and buttock. The simple expedient of cutting off the forward part of the bench, so that the engineman had to sit squarely facing forward, sufficed to reduce the number of cases of sciatica to the normal and to eliminate any especial prevalence of right-sided cases.

DISORDERS DUE TO HEAT

I have recently had a somewhat analogous experience in connection with the disorder that I have described as occurring in consequence of exposure to severe degrees of heat. I saw some years ago two peculiar cases of acute and violent muscle-spasm that had no analogues in medical literature; and, on more exact inquiry, I learned that both were in men exposed to unusual degrees of heat. Inquiry among other men who were severely exposed to very high temperatures in their work showed that nearly all men in such occupations are familiar with such attacks and that a large proportion of them have had attacks themselves. Through subsequently watching for such cases I have seen a number more, all exhibiting the same cause. I find through physicians whose work brings them into frequent touch with persons in such occupations, through the men themselves, and through their employers, that this, which is clearly a well-defined disorder, though not recognized in general medical literature, is astonishingly common in certain occupations; is of a good deal of importance from the economic standpoint, in its effects on the men and on the productiveness of the occupations in which they are employed; and seems to be always due to the same cause.

I have become convinced, also, that there are other important effects of heat that have not been generally recognized in medical literature, because attention has been too exclusively fixed on so-called heat-stroke and heat-prostration as consequences of exposure to high temperatures. More thorough study of conditions in cases that I have seen myself has shown instances of nervous lesions, such as focal meningitis, that were almost undoubtedly due to local or general exposure to intense heat, and I have seen likewise more or less serious effects on other organs. The literature of occupational disorders also contains numerous more or less well-substantiated statements as to the effects of heat in various ways, particularly on the nervous system.

More than seventy-five years ago Thackrah[4] said that MacTurk had described to him the frequency of various head-symptoms in workers in heavy metals—due, he thought, to heat; and Layet, a generation ago, described similar conditions. The statistics of some of the foreign sick-benefit societies and the writings of various authors indicate that several nervous conditions, meningitis, epilepsy, insanity and even suicide, are relatively common in some of these occupations. More or less serious circulatory weakness, anemia, acute and chronic disturbances of digestion, acute and chronic nephritis, respiratory disease and skin-lesions also appear to be unduly frequent in such persons. In addition to this, there has been much discussion regarding the incidence of cataract, retinal and choroidal changes, and chronic conjunctival lesions in glass-blowers; and similar conditions clearly occur also, though less well recognized, in iron-puddlers and other persons whose eyes are exposed to very intense heat. Dr. de Schweinitz states that he could often tell whether men working at puddling-furnaces were right-handed or left-handed by studying the effects of their work on their eye-grounds; and Röpke[5] states that Quint described to him cases of right-sided cataract in right-handed iron-workers and left-sided cataract in those who were left-handed.

The instances that I have mentioned are, of course, exceptionally striking, and a study of them has been unusually productive of results. I venture to state, however, that there are few, even of the commonplace occupations, in which more careful inquiry into the details of the work will not be repaid by a much broader understanding of some of the ills that people engaged in these occupations complain of—even though one may not often elicit points that are worthy of separate record in medical literature. For instance, it is known that those who work with heated tallow and other animal grease are subject to gastrointestinal disturbance, apparently from the volatile fatty acids that are given off and that the workers ingest and inhale. Recently I saw a man whose chronic gastroenteritis was almost certainly due to his work as a bullet-dipper, in which he was constantly exposed to the fumes of hot grease.

LOCAL EFFECT OF STRAIN

One of the first cases that aroused my special interest in the effects of occupation was an instance of that extremely common and endlessly varied subject, the local effects of strain; and it was, at the same time, an instance of the necessity for understanding quite precisely what the individual does. This man had signs suggesting contraction at the base of the left chest. He had had pleurisy, but on the right side. I was puzzled to explain his physical signs, but the man finally gave the whole explanation himself. He had been put down in the history simply as a machinist. He elaborated on this by saying that he was a "bit-and-auger fitter-up"; and further inquiry showed that he had spent most of his working hours for twenty years with his left arm advanced holding the piece of steel that he was fitting, and turning it forcibly every few moments in such a way that each time he did this he twisted the lower part of his left thorax inward.

[4] Effects of Arts, Trades, and Civil States and Habits of Living on Health and Longevity, Second Edition, 1832.

[5] Weyl's Handbuch der Arbeiterkrankheiten, 1908.

SOME OCCUPATIONAL CAUSES OF HEART STRAIN

These effects of strain, both the general effects and especially those that are exerted on particular organs, are daily experiences and frequently most interesting and illuminating; and the fact that they are every-day things, of course, makes them of greater interest. They are of particular frequency and importance in connection with circulatory disorders. Not long since I saw in quick succession a man with mitral insufficiency that appeared to be well compensated but that gave him much distress at his work; another man with aortic insufficiency that was giving him terrible distress when he was admitted to the ward but improved with surprising rapidity; and a third who had very dangerous myocardial failure with dilatation. The last-mentioned man had undoubtedly damaged his heart by alcoholism some years before, but neither with him nor with the others was there apparent any sufficient immediate reason for the development of symptoms. In none of them did the occupation as given in the record seem a sufficient cause for their symptoms. The first man was recorded as a carpenter; the second as a paper-cutter (starting and stopping a cutting machine); the third had a newspaper stand. Inquiry showed, however, that the first was a specialist in his trade in that he worked for large builders and that his duties consisted almost entirely in putting up heavy parts, and he had to lift every few minutes and put into place pieces weighing from one hundred to one hundred and twenty pounds. The second man proved to have as the chief part of his duties not simply cutting paper, but lifting and placing in the machine every few moments bundles of paper weighing from fifty to one hundred pounds; while the third man himself delivered newspapers to his clientele and this meant that in order to do his work quickly and hold his trade he set off twice daily with a package weighing fifty pounds or more (about one hundred pounds with Sunday editions), and went a circuit of two or three miles as nearly on the run as possible.

I would repeat that I am well aware that in dwelling on such simple things as important I am liable to the same comment that one of my friends applied recently to a distinguished man: "He learns out loud simple things that other persons know already." I mention them deliberately, however, for the very reason that they are the simple things that we meet with daily. Such things could be mutiplied *ad infinitum;* but I would especially note their importance in connection with chronic diseases of the joints, in a large proportion of which, more particularly in non-infectious cases, strain plays a most important part, especially in some of the apparently obscure cases of spondylitis and, of course, in flat-foot and knock-knees. Indeed, the latter are so common in some occupations that the laity, especially the Germans, have applied special terms to the disorders or infirmities produced.—*Bäckerbeine, Kellnerbeine.*

MERCURY POISONING

Finally, before leaving this part of the subject, let me give an instance of the fact that little points in the abstract information that we have acquired in some of our earlier studies not infrequently come into play in a very lively and human way in connection with occupations. The fact that mercury is volatile at ordinary room-temperature does not appear to be of much practical value in medicine until we see the exceedingly interesting results of its volatility in those who work with mercury; and recently this came even more closely home to me when I found a friend, who is much engaged in working with physical apparatus, exhibiting the remarkable erethism and apprehensiveness so common in chronic mercury poisoning, together with apparently causeless but persistent diarrhea. As an example of his nervous state, I would say that he told me that he left letters unopened for days for fear that they might contain some news that would distress him. He had an open jar containing mercury constantly on his office-desk, and had frequently spilled quicksilver on the floor of his office and of his bedroom, without paying any attention to it. About two-thirds of the twenty-four hours were spent in these two rooms. After he had had his attention called to this and had had the floors and cracks very thoroughly cleaned, puttied, and painted, and kept his mercury-receptacle tightly closed, his diarrhea and neurotic symptoms disappeared. They have since remained absent, now more than a year.

An undescribed, but perfectly rational cause of occupational mercury poisoning, which depends on the well-known fact that mercury is absorbed through the skin, is to be found in the custom that many dentists have of working up their amalgam in the palms of their hands. I have notes of two dentists who acquired poisoning in this way. I did not see either of these cases myself, but both are well authenticated by physicians.

Instead of being a frequently dull and profitless part of history-taking, occupations of even the most ordinary kind, when looked at in this way, become a constant source of useful information and of very interesting diversion. When viewed in this manner one appreciates also the second point that I would make, that is, that we may profitably look on the conditions in occupations as providing numerous massive experiments from which one can gain many broadening conceptions, and, furthermore, from a study of trades new facts that influence general medical conceptions may occasionally be gained ready-made, especially if the suggestions that they give are made more secure through animal experimentation and the precise studies that the latter permits of. In this way we can get answers to many questions that, approached by any other means, are much more difficult and at times impossible to elucidate, and that, in certain instances, have very important influence on our conceptions of some forms of disease and our methods of treating them.

It has been chiefly from study of occupations that we have learned the important effects of local and general strain in producing their very striking results on the circulation and other general functions or on especial local tissues. Occupations have also, of course, furnished practically all our knowledge of the effects of dust of various kinds, and our conception of the importance of commonplace things in producing disease must certainly be made much more emphatic by considering the dreadful evidence of the influence of very dusty occupations on health, evidence such as that found in the statistics of Sommerfeld,[6] Calwer,[7] and others regarding the duration of life of workers in stone, which appears to average only about thirty-three years. That is, as Calwer remarks, "a boy of fourteen taking up this occupation has a prospect of only about nineteen years more of life." Calwer puts the mortality of stone-cutters at over 5 per cent.; while the average among all persons studied was only a little over 1 per cent. Other figures showing the possible results of dust-inhalation in an astounding way are those of C. I. Birmingham[8] regarding the ganister-grinders in England, whose annual mortality reaches as high as 179.8 per thousand. Fortunately, this mortal industry employs but few men. Oliver has also given a most interesting description of the curious effects of gold-mining on the Rand in South Africa, an occupation that has had results only less deadly than ganister-grinding.

---

[6] Die Berufskrankheiten der Steinmetzen, etc., Berlin, 1892.

[7] Die Berufsgefahren der Steinarbeiter. Denkschrift an dem Bundesrat, 1901.

There are some exceedingly striking differences in the effects of different forms of mineral-dust. In a plant with which I am very familiar, the men stay for hours each day in an atmosphere so charged with dust from crushed ore that one can see only a few feet away; and yet, in over a decade, no marked bad results have appeared as a consequence. The difference is attributed by an able engineer who is familiar with the last-mentioned place, and who was also on the commission that investigated the miners' disease on the Rand, to differences in the physical characters and the solubility of the two forms of dust. It is doubtful whether there is not some other more peculiar explanation, however, for Oliver especially notes that certain of the miners in India, although they work with the same character of rock, escape the effects that are seen on the Rand.

LOCAL EFFECTS OF POISONS

It is also largely through our knowledge of occupations that we have learned of the curious way in which many poisons exert their effects on particular tissues, a point that is seen so strikingly in the fact that lead, in a large proportion of cases, picks out not only the nerves of the upper extremity, but a particular nerve in the forearm, in adults; while in children it more commonly attacks the nerves of the lower extremities. Arsenic, on the other hand, usually attacks most severely the nerves of the lower extremities; and while arsenic violently affects sensory nerves, lead scarcely does so at all. Methyl alcohol, in strange contrast to both these, shows a striking affinity for the optic nerve alone, a peculiarity that, curiously, is to a large extent shared by the newer organic preparations of arsenic, atoxyl and arsacetin. Facts like these have largely influenced our conceptions of toxemias, and help to point the way toward future precision in understanding and controlling toxemias.

There are a variety of other ways, also, in which important general conceptions have already been gained from occupations. A number of points of this kind that appear to me to be of great interest I have not seen emphasized. For instance, does it not greatly help to define our views of hysteria and neurasthenia (or of the condition that is now fashionably termed psychasthenia) to know that every conceivable symptom of these states occurs either in carbon bisulphid poisoning or in chronic mercury poisoning and that hysterical laughter and tears are common in chronic manganese poisoning. The symptoms usually disappear as the poisoning is relieved, and are, therefore, a direct effect of the poisoning. In chronic mercury poisoning there is in most cases absolutely no evidence of any organic disease that can be focalized, and the same is often true of carbon bisulphid poisoning. In the latter, however, there may be all forms of combinations of apparently functional disorder with the signs of organic disease, from the slightest to the most severe, and at times there remain permanent evidences of spinal lesion or persistent psychoses.

Such conditions properly make one suspect even more strongly than before that such states are *usually* due, not to mere psychic factors, but to some toxemias, and probably often to some special form of toxemia—when we consider that these neurotic symptoms are so frequent in certain known forms of poisoning and so closely dependent on them, while in other forms of poisoning they are actually uncommon. Surely the frequent toxic origin of such states is made very probable by Köster's experiments, in which he produced in rabbits, by exposing them to carbon bisulphid, glove-like areas of anesthesia; or, in other words, a characteristic hysterical stigma. This makes one feel even more strongly inclined to check the unbridled advance of pure psychotherapy in this country, especially when it is employed by non-medical persons.

On the other hand, we have likewise striking evidence that such neurotic states may at times follow on purely nervous and chiefly psychic influences—evidence provided by the studies of telephone-operators, for example, whose work is so full of strain that Wernicke[9] stated that every one of them who continues at work for several years becomes hysterical. This is probably an extreme view, but nevertheless Schuster,[10] Tommasi, and others, who also have studied this question, agree that hysteria and neurasthenia are most unduly common among these persons.

INFLUENCE OF OCCUPATION ON POSTERITY

In the half-medical and half-economic question of the influence of occupations on future generations, there are scarcely any more impressive points than those found in the fact that the mortality among the infants of mercury-workers is much higher than even the distressingly high figures given by the French and many other foundling asylums; and Constantin Paul's and Lewin's[11] studies of mothers who were engaged in working with lead and its salts showed even more dreadful effects on their progeny. Among a group of the latter women that Paul studied there occurred 123 pregnancies, of which 64 terminated in miscarriage, 5 in still-born children and 4 infants died after premature birth, while of the infants that lived longer, 20 died in the first year of life, 8 in the second year, 7 in the third, 1 later, and only 14 were living at the time of the report. Such effects are, I am sure, due in part to direct placental poisoning of the fetus or at times to poisoning through the mother's milk after birth, for lead has repeatedly been found in the fetuses of these women, in the bodies of their infants that died soon after birth, and in the milk of the lead-poisoned mothers. It is however largely due also to the effects on the child produced by the general degradation of health that this poisoning causes. This fact and the much broader fact that the parent has a profound physical responsibility toward the child are wonderfully illuminated by the observation that seven women who were the wives of men working in lead, but who were themselves free from lead-poisoning, had in the course of 32 pregnancies 11 miscarriages and 1 still-birth, while 8 children died in the first year, 4 in the second year, 5 in the third, 1 later, and only 2 lived. In these instances there was essentially no possibility of lead-poisoning in the fetuses and infants, and the dreadful effects must have been due to the disturbed health of the father. There are possibilities suggested by this of valuable studies on heredity, and it clearly shows that we tend nowadays to swing too much to the side of environment in explaining disease. Such studies show also that we probably think too quickly of lues when we get a history of habitual abortion.

---

[8] Quoted by Oliver, loc. cit.

[9] Monatschr. f. Psychiat. u. Neurol. Ergänzungsheft, xvii.

[10] Weyl's Handbuch der Arbeiterkrankheiten, 1908.

[11] Berl. klin. Wchnschr., 1904, p. 1074.

These latter points that I have mentioned as being illuminated by a study of occupations are semi-medical and semi-philosophical. There are many more of the same kind that are of very great interest, such as the direct influence of various occupations on the occurrence of alcoholism, sexual immorality, and other forms of depravity; the effect of employment on home conditions; the influence of the latter secondarily in producing depraved nutrition and its consequences, especially tuberculosis; and many other such questions. Besides these, however, there are numerous points that are open to investigation by the more precise methods of the laboratory, and particularly by animal experimentation; and in some instances such studies are perhaps capable of settling or greatly clarifying important questions.

Opportunities for valuable study of this sort have repeatedly gone begging until the matter was cleared up in other ways. For instance, there is no more important practical fact in controlling infectious diseases than that which has been borne in on us in overwhelming fashion by the studies of recent years—the commanding influence in the propagation of these diseases of more or less direct contact with the sick. Filth, important as it is in providing conditions favorable for the spread of infections, has taken a place of secondary importance in managing them, for contact can never be controlled, but only lessened, through controlling filth. The conviction that this was likely to be true and the stimulus to undertake the work that would prove it might have been gained much earlier than it was had thoughtful attention been given to studies such as those of Augustus Gay[12] on "nightmen" scavengers and dustmen, which showed that, while these men spent their lives chiefly in dealing with filth, they exhibited an unusually good average health; and the limits of the relation of dust and dirt to disease are made much clearer by the fact that Oliver[13] reached similar conclusions from his studies of the "dust-women" of London, whose occupation consists in rescuing petty trifles from dry refuse and sweepings. Our general position at the present day in regard to this whole matter of infections was long ago stated tersely and clearly in Gay's conclusion that "filth is rather the *nurse* than the *parent* of fever." Earlier appreciation of this would inevitably have led to earlier appreciation of the actual importance of contact.

Again, it is not improbable that at least one, and perhaps more, of the valuable observations of the Pawlow school and of those who have followed Pawlow might have been brought out years before they were had thoughtful attention been given to a very old method of preventing lead-poisoning, which probably has some virtue. More than one hundred and twenty years ago Richardson[14] said: "In order to defend themselves from the bad effects of lead, all those that are in any manner exposed to its daily influence should eat some fat broth. or bread spread thickly with butter or lard, before they enter on their work." He also recommended salad-oil, likewise to be taken fasting. The latter measure is, I know, still used in some lead-works, and in some of them it is required of the men, with, it is claimed, good results. Not improbably it does good; at any rate had the suggestion that this point gives been followed up it might have been shown long ago, instead of only in recent years, that fats depress the secretion of gastric juice and have important dietetic use because of this fact, and it might likewise have been found as a corollary to this, long before Oliver, Bedson and Best actually pointed it out, that the hydrochloric acid of the gastric juice is the chief factor in getting the insoluble lead salts into solution, and thereby causing their absorption. It is an interesting fact, also, though not a very relevant one, that other observations than those mentioned indicate that the gastric hydrochloric acid is a dominant factor in leading to lead-poisoning. Carnivorous animals are much more subject to lead-poisoning than are herbivorous when living about lead-works, very probably because the former have a much higher percentage of hydrochloric acid than the latter.

RELATION OF OCCUPATION TO MALIGNANCY

There would appear to be an opportunity, also, to advance our knowledge of cancer in ways that might be very useful through studying occupations more accurately. There is sufficient evidence that chimney-sweeps and workers in tar pitch and paraffin get cancer from the substances with which they come in contact in their occupations to make it desirable to attempt more earnestly than has yet been done to determine what the nature of the peccant substances is—whether chemical or possibly micro-organismal—and the character of the cell proliferation that they produce in the earlier stages. There have been a series of studies of this matter, but not convincing ones. It appears to me to be not a question merely of chronic irritation of the skin in any of these conditions; for in a considerable variety of occupations severe skin irritation is common, as in bakers, and in a number of them (chrome-working especially) violent non-malignant skin lesions occur frequently, but in only a very few occupations do progressive proliferative changes in the skin appear to be set up. A similar tendency to cancer of the skin prevails among gardeners and agriculturalists, who have a very abnormally high incidence of this disease. There is evidence that this is not true of these occupations in certain regions, as in Erfurt (Loth: Weyl's Handbuch), but this may indicate the interesting possibility that the exciting cause is limited to certain localities.

Such are some of the suggestions regarding investigations of general significance that are to be obtained from a knowledge of occupational conditions. There are many other suggestions of interesting studies that relate to especial disorders themselves, rather than to general medical questions. An important instance of this is carbon monoxid poisoning. This is, in the first place, probably the most important form of suicidal poisoning at present; it is a somewhat frequent form of accidental poisoning from broken gas-mains or house-pipes, Dr. R. S. McCombs having seen over 500 such cases, he tells me, in a few years in his work with a large gas company. It is also an occasional cause of more or less serious danger to families from poor drafts in heating apparatuses. Beyond this, however, it is a somewhat common form of intoxication in men working in iron and other mills and furnaces, in miners, in those working in deep excavations, in those employed in the commercial use of electric furnaces (which are becoming of considerable

---

13. Oliver: Dangerous Trades, etc., 1902.

14. Chemical Principles of the Metallic Arts, with an Account of the Principal Diseases, etc., Birmingham, 1790.

industrial importance), and even in laboratories in which the electric furnace is used in investigations. The poisoning occurs, furthermore, in men in fire companies and a variety of other occupations, the most recent source of it being the exhaust of automobiles—chauffeurs and car owners whom I know having repeatedly been mildly overcome when running the engine of a motor-car in a small, closed garage for some time and serious cases having been reported in noteworthy number. It has even caused somewhat serious accidental poisoning of the occupants of a closed automobile in which there was a defect in the floor above the exhaust (Oliver). For a subject that has so much clinical interest, especially to those engaged in hospital practice, and one that relates to such a variety of occupations, the literature is in a curiously unsatisfactory state and is much in need of a systematic overhauling and improvement as regards sources of the poisoning and many points in the clinical history and treatment, and a determination of the importance or lack of importance and the clinical characteristics of chronic poisoning of this sort, from both accidental and occupational sources, is especially desirable.

There is no dearth of subjects to work on, and the problems vary from those that are very simple to those that are so complex that one can scarcely hope to add more than slight fragments of knowledge. We do not need to search for a subject to work on so much as we need to avoid the superficial methods of reaching conclusions that have been so common in this class of studies. Thackrah very properly said of Ramazzini,[15] who was the earliest writer on this subject, that he had too strong a disposition simply to investigate the conditions surrounding an occupation in a general way, to decide that certain results must occur, and then to describe these results as occurring—a tendency that Thackrah modestly says he has often detected in himself. It is a tendency that may be seen widespread in medical literature, and it has caused many erroneous statements to become traditional.

EMPHYSEMA IN GLASS-BLOWERS

For instance, the teaching that glass-blowers and those who play on wind instruments are very subject to emphysema is quite general; but the most recent studies of the musicians in the German military bands, and the studies by Prettin and Leibkind[16] of glass-blowers who had been at this occupation for at least ten years, are directly opposed to this. The latter showed that only five of 230 glass-blowers had emphysema, and it was probable that in all these cases it was due to other causes than the glass-blowing. These observations are concurred in by Schmidt and others. This, then, is apparently a tradition and not a fact. It is also possibly an illustration of the adaptability that tissues frequently exhibit to an extra tax, so long as they are not diseased, though it appears to me that careful observation of these persons shows that the strain comes very much more on the mouth cavity than on the lungs, and the mouth often showed marked results—hernia of cheeks and perhaps dilatation of Steno's duct.

INDUSTRIAL HYGIENE IN THE UNITED STATES

Just as a more precise study of individuals in relation to their occupation leads one to some actual investigation of occupations from a medical standpoint, so does it almost necessarily lead one to the third point of my remarks, namely, the taking of a sociologic as well as a medical interest in the matter. In conclusion, let me emphasize some reasons for more thorough studies of the hygiene of occupations in this country, in order that special provision may be made for the circumstances that exist here. When one considers all the attention that hygienists in nearly every other highly civilized country have given to the study and control of the ill effects of occupations, and when one merely reads over some of the many regulations that have been established abroad to improve conditions, it lowers one's pride to realize that in America the national government has made no noteworthy original studies of the question, and the only government contribution of importance is the recent report from the President's Homes Commission, written by Dr. Kober, in which, however, he was obliged to get his facts not from government investigations, but wholly from other sources. Of the states, Massachusetts is the only one that has conducted an investigation that deserves any special attention, and this was naturally limited in its scope. As to regulations, these are exceedingly few in number and inefficient, except as regards a few striking points such as the regulation, in a limited way, of the hours of work, the danger of accidents, etc. Indeed, in regard to most occupations as they exist in this country, we have no systematic information from either government sources or individuals that would be sufficient to base just and comprehensive laws on. In considering occupations from a legal standpoint, as in using this question in our medical practice, we are in almost all instances dependent chiefly on information that comes from European writings, and conditions are known to be in some instances very different in this country, and they are probably different in numerous instances.

A concrete illustration of this latter point is seen in connection with phosphorus-poisoning. This furnishes, also, a striking illustration of the fact that industries in this country are very frequently controlled by great corporations, while abroad they are still often found to a large extent in the form of small domestic industries. Matchmaking is, in Germany, still largely carried on in little home factories, and when the recent law making it illegal to use the poisonous white or yellow phosphorus was passed it was felt necessary to make this prohibition apply to the home industries, because many of the worst cases of poisoning came from these sources. It was, however, considered necessary at the same time to avoid killing off the little home factories, because of the numbers of people that were engaged in them. Hence a clause was introduced which exempted these little factories from the provisions of the patent on the methods of making safety matches. So different are the conditions in this country that at the present time almost the whole match-making industry is confined to one large corporation, and this concern has so thoroughly recognized the valuable effects of hygiene from both the humane and the economic standpoint and has established such effectual measures that phosphorus-necrosis has almost disappeared in their factories even in those who work with the poisonous forms of phosphorus, a result that at one time was considered impossible to achieve. The concentration of capital that is so remarkable a feature of the industries of this country has, therefore, in this, as well as in some other ways, made our conditions greatly superior to those in most other countries. In many instances, however, it makes them worse, for, if a corporation be rapacious, the larger it is the worse its evil effects. That the conditions are wonderfully good in individual corporations but astonishingly bad in others, and, further, that there is a sad lack of power to make them good when they are bad, is shown better perhaps than it could be shown by any native studies, through the dispassionate report of a foreigner, Dr. Gallard,[17] who was sent here by the French government to determine what the conditions are in this country as regards industrial hygiene. He speaks with enthusiastic admiration of the remarkable things that certain large concerns have done for their employees; but, on the other hand, he discusses with courteous but severe condemnation some other conditions, and he refers with considerable amazement to the *laissez-faire* attitude of the government and the general public. Especial condemnation is visited on one concern that makes a valuable safety device, but does not use it in the factory where it is made, although it is specially needed there!

[15] De Morbis Artificium Diatriba, 1703.
[16] München med. Wchnschr., 1904.

There are various other things than those mentioned that make conditions in this country very different from those abroad. Indeed, there are certain occupations that are more or less important as causes of ill health abroad that practically do not exist here, at least in a form to cause the same sort of disease. There are, on the contrary, others that are of importance in this country, but are scarcely touched on in foreign writings.

The much greater use of machinery here than abroad, in replacing hand labor, is an element of much importance. I visited, for instance, a certain paint factory, in investigating some phases of occupational lead-poisoning, and found that only one man was at all seriously exposed to lead. Machinery, indeed, did so much of the work that fewer men were employed in the large factory than at the desks in the offices. In some instances, as in this, the effects of such modern machinery are extremely good. In others they are bad, because they throw an exceptional amount of physical or nervous strain on a few individuals, as, for example, in running some of the more complex textile machines, and any good physical effects of such improvements that may occur are, in this country, too often purely incidental to the commercial value of the changes in technic. The deliberate introduction of such measures because of their hygienic effects has been much more extensively practiced abroad than here. There is in Europe a very much more general requirement of efficient means of ventilating and cleaning working-places and of other important general measures; and also of many special ways of overcoming the particular evils of particular occupations. Power is very frequently given by law to see that these measures are carried out. Furthermore, the frequency with which they offer in several foreign countries such philanthropic measures as providing means for working mothers to nurse suckling infants is admirable, as is the frequency with which they demand less taxing work or entire rest for women in the latter part of pregnancy and in the puerperium.

When contrasted with foreign conditions, our nation seems in many ways to be generations behind numerous other civilized countries. I would have it understood, however, that I do not advocate as the dominant means of overcoming the evils that exist the enactment of special laws. Laws are essential, in order to control those who have neither altruism nor breadth of view; and that they may do great good is seen in the fact that in France they have long had careful regulations governing the manufacture of lead products, with the result that in Paris, one of the two chief centers of the lead industry in that country, the cases of industrial lead-poisoning admitted to hospitals a few years ago averaged only 13 per annum (Gautier), while in Klagenfurt, Austria, also a center of these industries, but in a country where they are essentially uncontrolled, the number of attacks of lead-poisoning in one factory averaged nearly 1½ per annum for each man employed. The justification for laws because of the loss that occurs to the state is seen in the fact that in the one city of Vienna, among the pottery-makers, painters, printers and typesetters, about 45,000 persons in all, and engaged in occupations that by no means head the list in the danger of poisoning that they entail, the annual loss of labor through lead-poisoning alone was over 43,000 working days.[18] In this country this would probably mean at least $100,000 of direct annual loss, besides the confusion and inefficiency lent to the work by constant changes of employees. When one considers that tuberculosis and other diseases that are secondary consequences of the poisoning that occurs in such occupations produce an even greater loss of labor and expense to the state, the economic effects of the evil conditions of occupation and the desirability from the standpoint of the commonwealth and nation that they be lessened become quite apparent.

As a very striking illustration of the influence of laws, I would mention that the English pottery workers showed per annum but 1.5 per cent. of lead poisoning, while the Viennese engaged in the same sort of work showed 34.1 per cent.—a difference that appears to be almost entirely due to the fact that there are no laws controlling this industry in Vienna, while the English laws, particularly in regard to the fritting of the glaze, are strict. Again, Gautier, as I stated, mentions that in Paris, one of the two main centers of the white-lead industry in France, the total number of cases per year of industrial lead-poisoning admitted to hospitals during two years was only 13, owing to their very careful regulation of these industries, while we have had in one hospital in Philadelphia, the Episcopal Hospital, each year many more than this number of cases from one such factory.

APATHY OF THE WORKER

But regulation is not the first, nor is it the only important step. This is especially true for this reason, if for no other: Laws or voluntary altruism may lead employers to make regulations and to provide special hygienic facilities, but the greatest difficulty in many instances is in getting the working people to take precautions intelligently. Even when any time consumed was paid for as if it were labor, I have known employees to object obstinately to regulations demanding bathing, for example; and those who have devoted much time to the study of occupational conditions frequently bewail such difficulties. Employees think the precautionary measures are too much trouble or require too much thought, or they often feel that any regulations interfere with the rights of a free American citizen, or they have other reasons. Very often they object simply because the regulations are new and are against their traditions. This attitude and the selfishness and apathy of some employers can best be overcome by finding out what the exact details of the process are, so far as they affect health, and then pointing out to both employers and employees how these difficulties can be overcome. Employers are very quick to see the economic value of hygienic measures if they can be convinced that they actually accomplish results, and especially if it is clear that they are in themselves ultimately accompanied by reduced expense. Suitable laws will come much more quickly and more certainly when there has been accumulated general knowledge of the conditions that actually exist in this country and of the things that are needed in correcting them. This must originate in very large part from physicians, for they alone have frequent occasion to see clearly what the effects are. It is because, with very little effort or expenditure of time, almost every one of us can not only increase the precision of his own clinical methods, but can also contribute to a growth of knowledge that will tend enormously to benefit human kind that it seemed suitable to digress, in this latter portion of my remarks, into matters that are quite as much sociologic as medical.

THE RESPONSIBILITY OF THE PHYSICIAN IN THE CAMPAIGN AGAINST TUBERCULOSIS[*]

JOHN GIRDWOOD, M.D.
Assistant Physician in the Phipps Tuberculosis Dispensary, Johns Hopkins Hospital; Physician in Charge, Christ Church Tuberculosis Dispensary.
BALTIMORE

The subject of tuberculosis has been considered from a great many points of view, but I do not think that the responsibility of the family physician has been sufficiently emphasized. The object of this paper is to bring existing conditions to the attention of this society and to make an appeal for the more faithful recognition of our very great responsibility in the campaign against tuberculosis.

The apathy, indifference, and often hostility, displayed by so many physicians is one of the greatest obstacles to the successful prosecution of the fight against the greatest enemy of the human race.

The public has a right to expect of us that we, individually and collectively, do everything possible to protect it; people are looking to us to devise means to protect them in the home and the workshop; they expect us to instruct them, in our capacity of family physicians, in the means to be employed in its prevention.

The active work of the campaign has been conducted by a few earnest and sincere men, but it has not met the interest and thorough cooperation of the great majority of general practitioners. Unless the profession as a unit support this movement its consummation will be very materially delayed.

We have often failed to recognize the social aspects of the disease. We have not insisted on our patients giving up their work, in the early stages of the disease, before they become incapacitated; we have not pointed out the sound business principle of this course.

We have sent our patients to Colorado and California and other health resorts, without sufficient inquiry into their financial ability to meet the increased expenses in those places; we have encouraged the hope, which few of them realize, that they may find gainful occupation there; the cry has come to us from those places to keep our patients at home, and we must heed it.

Have we realized the possibilities of home treatment? I think not. The essentials of treatment—fresh air, good food and rest—are by no means universally prescribed, but they should be, just as much as quinin in malaria or mercury in syphilis, for they approach nearer to a specific than anything in the Pharmacopeia. It is wonderful what results they will produce in the home of the patient, many times under very unfavorable conditions. We do not allow a typhoid patient to get up until his temperature is normal; then why a tuberculous patient? No objection on the part of the relatives or friends should deter us from insisting on these essentials of treatment.

The responsibility of the physician embraces his obligation to his patient, to society and to the state.

RESPONSIBILITY TO THE PATIENT

As the family physician is generally the first to be consulted, he has the opportunity first presented to him for early diagnosis, and as the subsequent career of his patient, both of health and fortune, depends on the early recognition of the disease, he has a very great responsibility.

A few very important helps to diagnosis are:

1. Careful attention to early symptoms.
2. Thorough physical examination.
3. Examination of sputum.
4. Tuberculin tests.

1. *Careful Attention to Early Symptoms.*—Among these may be mentioned cough, afternoon fever and loss of weight.

Cough is generally the symptom that prompts the patient to seek advice. It may not be constant, but may occur only in the early morning, on rising, or at night. When it occurs in a person previously healthy it should be looked on with suspicion. This symptom should be more seriously considered than it habitually is by a great many men, especially when accompanied by a slight elevation of temperature.

Afternoon fever will not be detected in the early stage, unless it is looked for; therefore the necessity for the use of the clinical thermometer. This simple procedure is frequently neglected. If a slight elevation of temperature is found or suspected it is the proper thing to give the patient a thermometer, with instructions in its use, and have him take his temperature every four hours during the day and keep a record. The great majority of patients will be thoroughly capable and willing to do so, and it will be a great help to diagnosis.

Loss of weight is a very important symptom. The patient should be weighed by the physician himself, so that it is important that the latter have scales in his office. This symptom, associated with cough and afternoon fever, will add another very important link in the evidence.

There are many other important symptoms, which I have not time to consider in detail, such as spitting blood, malaise, fatigue after the usual work, loss of appetite, etc. They should each be carefully considered.

2. *Thorough Physical Examination.*—This cannot be too strongly insisted on. Many early cases are overlooked because the doctor does not remove the patient's shirt. It is absolutely impossible to detect the early physical signs without a careful and thorough examination, which may have to be several times repeated, before definite lesions can be detected.

The physical examination is the most important of all procedures. Although by itself it may leave us in doubt, through physical examination, in association with the symptoms mentioned above, we may be able to arrive at a definite conclusion.

3. *Examination of Sputum.*—Although tubercle bacilli are not found until there has been some destruction of lung tissue, they will often be found very early in the disease, even when the symptoms are slight. When they are found we shall be able to give positive proof of the existence of the disease. They should therefore be sought; still, this simple procedure is neglected by a great many physicians. The city provides a laboratory where the examination is made, yet the number of physicians who availed themselves of this privilege last year was but 393 out of a total of about 1,300 in the city of Baltimore. Allowance must be made for those who do not see tuberculous cases, for those engaged in specialties and for those who have sputum examined elsewhere; still I think it may be safely estimated that 50 per cent. of practitioners do not avail themselves of this privilege. But 1,932 examinations were made in this laboratory in the past year.

Another proof to be kept in mind is that failure to find tubercle bacilli in the sputum does not exclude the possibility of the disease, as they may be absent from the sputum, or they may not be found microscopically. Repeated examinations may be necessary. Their demonstration is positive proof of the existence of tuberculosis, but we should not exclude it when they have not been found.

4. *Tuberculin Diagnosis.*—The diagnosis of tuberculosis by the use of tuberculin is now within the reach of the general practitioner. He may employ the ophthalmic or the skin test, or may use tuberculin subcutaneously. There is no reason why these valuable tests should not be generally adopted, the only precaution necessary being the proper attention to dosage.

It is only by careful attention to all these points that an early diagnosis is possible, one being corroborative of the other.

Another important measure which should be more generally employed is the examination of persons who have been exposed to the disease, either in their own homes or elsewhere. I have on many occasions discovered early cases by this means.

Tell the Patient the Truth.—After we have made a definite diagnosis, it is our duty to tell the patient the whole truth. It will not be so great a shock to him, if we are able to say that the disease is in its early stages, and that proper treatment, adopted at once, will restore him to health, as to wait until the disease has advanced, when he discovers the truth himself, or is told by another physician, and when we cannot honestly give him a favorable prognosis. There is no justifiable excuse for secrecy; the theory that it does the patient harm to know the truth has not been the experience of those who are working in dispensaries and sanitariums. It is impossible to institute proper treatment unless the patient understands the objects to be obtained; consequently those who hide the truth are not giving their patients the full benefit of their knowledge. A patient will not take the proper measures to protect those around him, unless he knows that he has a contagious disease, which he can communicate to them.

A great many doctors consider it poor business policy to tell the patients, as they may lose the patronage of the latter. In this they make a great error, as they will surely lose the patients' confidence and respect; when the truth comes to the patients they are very likely to say that the doctor did not know, or that he deceived them.

It is not sufficient to tell the patient that his lungs are weak, or that he has catarrh of the lung, or that he has a deep-seated cold, which will clear up when warm weather comes, or a great many other indefinite or meaningless terms, which many men do, but they should be told in terms which they understand; the disease should be called consumption. As I said before, it does no harm, and the doctor is saved from subsequent humiliation or abuse.

That the patient is not told the truth is the observation of everyone who has attended many advanced cases. It is a disgrace to the profession when a patient, writing to the public press of his individual experience, relates that he consulted four or five doctors, among them a personal friend, and also visited a dispensary in our city, that none of them told him the truth, and that in consequence he was allowed to subject his family to infection for a considerable length of time, when he should have taken measures to protect them, and should himself have been under proper treatment.

The time is not far distant when the doctor will be held legally responsible when he neglects the proper measures for diagnosis, or hides the truth afterward. I do not think it would be difficult to convince a jury of the doctor's responsibility and liability, if he failed to examine the sputum, when it could be shown that that was all that was necessary for a diagnosis.

Another practice that has been carried on by some is to deny to the patient the existence of tuberculosis, when the latter has been informed, either at the dispensary or by a conscientious physician, the result being that all prophylactic measures were discontinued, the patient given false hope, and the influence of the dispensary decidedly diminished in the neighborhood. Such a case has recently come under my personal observation. Such a practice cannot be too severely censured.

RESPONSIBILITY TO SOCIETY

The further the obligations are removed from the individual the fewer the number of those who appreciate them; consequently a larger number fail in their obligation to society. One of the principal reasons for this is that the individual must often sacrifice his inclination for the good of society. The old Mosaic law which required the leper to cry out "unclean" at the approach of anyone may seem a hardship, but it was the means of preventing the spread among the Jewish nation of a very loathsome disease. We are unwilling to subject our patients to partial or complete isolation, whereas this must become the most effective means in preventing the spread of the disease. We must discourage marriage among consumptives, unless the disease has been arrested for a considerable time. We must prevent a tuberculous mother from nursing her babe, not only because of the ill effects on the mother, but because of the very great danger of infecting the child. We must protect the laundress who washes infected clothing and the woman who cleans the rooms. We should protect the family whose cook has tuberculosis. All these and many other obligations belong to the physician and should be assumed by him.

RESPONSIBILITY TO THE STATE

This requires that the physician fulfil the requirements imposed on him by law. Has he done so? The advantages of registration no longer admit of discussion, and this has been enacted into law. It is therefore the duty of the physician to register his cases as soon as he makes a diagnosis. I cannot see what possible objection he can have to doing so, yet of over 2,200 physicians in this state, only 595 reported one or more cases to the State Board of Health; most of these reported one each, and not more. It may be only fair to state that probably 25 per cent. of the physicians are not in active practice, or may not have tuberculous cases under their care. Assuming that there are 1,600 physicians in active practice in this state (Maryland), who see cases of tuberculosis, but 595 or about 37.5 per cent. are fulfilling the requirements of the law.

These 595 physicians reported 1,483 cases to the State Board of Health, while seventeen dispensaries and hospitals reported 1,130 cases and the tuberculosis nurses reported 870 cases. The Phipps Dispensary alone reported 33 per cent. of all the cases.

Although I have been unable to obtain the exact figures, I think that I am conservative when I state that 90 per cent. of all cases reported to the State Board of Health are in the second or third stage of the disease, and not more than 10 per cent. of early cases. This would indicate that the diagnosis is not made early, or else that the cases are not reported early.

Some men allow their cases to be reported by the dispensary or the nurse, because they do not care to take the time to fill out the very excellent form of instruction required by the state board of health, for which the state allows a fee of $1.50, and which is no more voluminous than that required by every fraternal or beneficial society, and for which he receives a fee of $1.

I wish to make a plea for a more general observance of this requirement. There should also be a more general observance of the law requiring rooms occupied by consumptives to be fumigated when they are vacated either by death or removal. No objection by householder or landlord should deter us from this obligation.

There are several reasons why these conditions exist: (1) incompetency; (2) carelessness; (3) economic considerations. There is no justification for any of these.

1. *Incompetency.*—There are abundant opportunities for every practitioner to acquire sufficient skill in physical diagnosis, if he will avail himself of them; but he need not be a skilled diagnostician; if he will faithfully watch the symptoms mentioned above he will generally be able to make a probable diagnosis. If he be in doubt, consultation is always available.

2. *Carelessness.*—This is thoroughly inexcusable, but may be in a great measure overcome by the adoption of a definite plan of examination, which should be recorded.. Such a procedure will require very little time, when once adopted as a habit.

3. *Economic Considerations.*—These are rather more difficult to combat, the enormous increase in the number of practitioners, the multiplication of dispensaries and hospitals, the increased cost of living, the reduction of fees, and many other considerations—all combine to make the practice of medicine less remunerative than formerly, and thus increase the temptation for irregular and unprofessional practice, but, as I have tried to show, even from this standpoint it is a short-sighted policy, that will react to the disadvantage of the one pursuing it.

In conclusion I will appeal to all members of the profession to uphold their traditions for honesty and unselfish devotion to the interest of their patients. I appeal to them to recognize the fact that they are the most important factor in this great campaign, which has just fairly begun, but which gives promise of developing into one of the most popular movements that has ever existed. I appeal to them to recognize their obligations before they are compelled to do so by popular demand.

102 East Twenty-fifth Street.

THE TREATMENT OF CANCER OF THE UTERUS WHEN TOO FAR ADVANCED FOR CURE BY EXTIRPATION OF THE UTERUS *

H. J. BOLDT, M.D.
NEW YORK

Although my primary purpose is to speak of the treatment of inoperable cancer of the uterus, a few words regarding the general subject of uterine cancer may not be out of place.

Most important in this connection, it seems to me, would be the formulation of some plan whereby the number of women hopelessly so afflicted may be lessened. This can be accomplished only by teaching women that there is no one symptom peculiar to cancer alone. While it is true that the disease is more likely to occur about the climacteric period, yet no period of life is exempt from it. Its approach is so insidious that, when symptoms of an alarming nature manifest themselves, the disease is usually so far advanced that it comes under the head of "inoperable cancer." Women must be taught to apply to their physicians on the first manifestation of a pelvic symptom at variance, even though very slightly, with their normal condition; in particular a variation of the menstrual function, including a leucorrheal discharge, and especially if their age be past 40 years; though, let me reiterate, they must be made to realize that no age is exempt from uterine cancer.

In Germany women have been taught by Duehrssen and Winter, especially by the latter, the necessity of early consultation with their physician, when any abnormal symptom presents itself. The teaching by Winter has been through the lay press, with the result that already in many parts of Germany there is a decreased percentage of "inoperable cancer" patients. Physicians, too, have learned the necessity of carefully examining every patient that applies to them with such symptoms, and the wisdom of expert consultation whenever there is question as to the diagnosis. The American conception of what is ethical is somewhat at variance with that of Germany; yet similar methods must be adopted here if we are to gain early practical results. It is for such men as those composing this Section to determine on the best means of diffusing information among women without violating the standard of ethics, and I would earnestly suggest that a committee be appointed to consider this important matter and report its conclusions, with a view to letting the main body of the Association take such action as may be most useful to womankind, and at the same time strictly ethical.

I am convinced that only by such means can we hope to lessen the mortality from cancer of the uterus, and that the early recognition of the disease, followed by prompt proper intervention—not the very extensive abdominal operations now practiced by many, particularly in Germany—will prove an important agency in decreasing the death rate from this malady.

Since the revival of the abdominal route for the extirpation of cancerous uteri, and the employment of the modified paravaginal section for extirpation by the vaginal route, the number of patients left to die of the disease without any surgical attempt at cure has been lessened. Nevertheless there is a large number of women for whom nothing can be done, save palliative treatment.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

It is unfortunate that women with inoperable uterine cancer should be undesirable patients at most hospitals, for proper hospital care is fully as necessary to these unfortunates as to those still in a condition permitting of an attempt at radical removal of the disease by surgical intervention. It is, indeed, pitiful to see how little is done to mitigate the misery of these sufferers; how frequently every shadow of hope is taken from them by some unfeeling person—very often the physician—who does not withhold the truth as to their condition.

The palliative treatment of cancer becomes especially important when we recall that, by preventing the nutrition of the cancer cells, we cause them to undergo retrograde metamorphosis and thus destroy their activity. We know from the experience of the late John Byrne and many others, myself among them, that even in carcinomatous uteri of long standing the further progress of the disease may be checked by proper heat application. It has been asserted by some, particularly by Byrne, that cures even have been brought about by such means, the cancer cell having very little power of resistance against heat. The late Lawson Tait asserted that he had seen some spontaneous cures of cancer. I myself saw such an instance: a pathologist of international repute had made the positive diagnosis of cancer, and so far as the macroscopic appearance of the tumor went, his opinion seemed correct. When a few years later the woman died of some ailment of a different nature, the postmortem failed to show evidence of the tumor found by me at the time of making the abdominal section. The carcinomatous structure had disappeared. This observation, personally made, would have a tendency to verify the statement of Lawton Tait, that an exploratory abdominal section, in some instances, suffices to bring about a cure of intra-abdominal cancer. In addition to the case verified by the report of a prominent pathologist, I saw another tumor, which, from its macroscopic appearance and from the clinical course of the patient prior to the doing of the abdominal section, was likewise an inoperable cancer. Not only I, but Drs. John Wyeth and Sims, who were present at the time the exploration was made, thought that the tumor, for the purposed extirpation of which the exploration was made, was a carcinoma. The abdomen was closed, and then, for more than ten years, I observed the woman. The tumor gradually disappeared, and three years later not a vestige of it could be felt. Moreover, the woman, who was emaciated at the time of operation, became robust, the picture of health, without further treatment. The family had been told, after the exploratory operation, that the patient would probably die within a year from the cancer which, even before the abdomen was opened, was thought to be present. Inasmuch as no histologic report from an excised piece of the neoplasm was obtained in this instance the clinical diagnosis lacks confirmation by the microscope. There can be no question, however, that the system, under some circumstances, checks the proliferation of cancer cells and occasionally succeeds in destroying their life

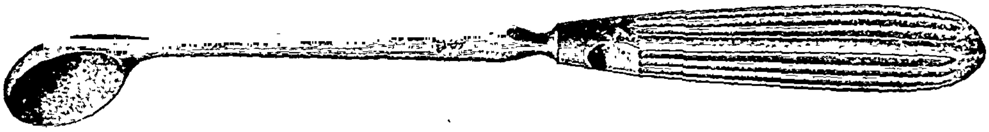

Fig. 1.—Heavy curette or "cancer spoon" for scraping a carcinomatous uterus.

Czerny[1] reports an instance of "inoperable" cancer of the vaginal part of the cervix, for which a palliative operation was done. Re-examination of the patient, five years and three months later, showed her to be absolutely cured. He mentions several other instances of spontaneous cure of cancer.

Lomer,[2] of Hamburg, in his article on the curability of carcinoma, also quotes cases of similar cure.

Chrobak[3] has observed a number of patients on whom palliative operations were done, with entire recovery following.

It seems certain that small cancer remnants left in the body are sometimes taken care of by the system. What the conditions are in such instances no one has yet determined. An example illustrating this was the case of an incipient cancer of the tongue, for which I operated in association with the late William T. Bull in 1888, when I was still doing general surgery. The clinical diagnosis was verified by the microscope, and it seemed later from the macroscopic appearance of the tongue, and also from a microscopic examination from the edges of the specimen removed, that a small remnant was left behind; yet the patient eventually made a good recovery, and five years later was living without evidence of the disease.

Clinical experience has shown beyond doubt that palliative treatment may benefit cancer patients by directly destroying the cancer cells with the agent used, and perhaps by forming a protection against the cancer proliferation.

As to palliative treatment by surgical means, the disease in some instances has advanced too far even to allow such a course to be considered, because its application might—yes, in all probability would—leave the patient in a worse condition than before the intervention. We know that in young persons especially the neoplasms grow rapidly, so that the nutrition of the tumor does not keep pace with its rapid growth. The result is that the central part of the tumor breaks down because of the sparsity of blood vessels there. Hence the destruction may have proceeded so far as to make it hazardous for us to use proper energetic surgical means to correct the symptoms caused by the breaking down of the new growth, because of the danger of injury to the bladder or the rectum.

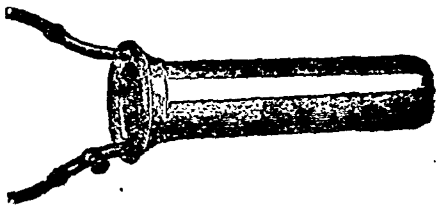

Fig. 2.—Metal speculum with double hull, for use in cauterizing the uterus.

Some surgeons have gone so far as to assert that a refusal to do a radical operation for cancer of the uterus is justifiable only after an exploratory abdominal section has shown it to be impossible, except in those cases in which it is obvious that the bladder or the rectum is already affected. I confess that I consider this going too far, for, while we may still be able to complete the operation, I can not conceive what the patient is to gain, even if she does recover primarily. I look on an operation simply as a surgical possibility when uterine cancer has passed beyond the boundaries of the uterus to such an extent that palpation can readily show that it has done so. I prefer to resort to a palliative operation with a curette and a cautery under such circumstances, and I believe that the results are just as satisfactory as to the longevity of the patient, and far better as to immediate mortality; for the curette and cautery operation should cause no deaths directly, unless from the anesthetic.

---

[2] Lomer, R.: Zur Frage der Heilbarkeit des Carcinoms, Ztschr. f. Geburtsh. u. Gynäk., 1903, l, 305-384.

[3] Chrobak, R.: Zur Behandlung des inoperablen Uteruskarzinoms Wiener klin. Wchnschr., 1905, No. 38.

Before beginning the surgical intervention with a curette and a cautery, a careful examination is essential to determine, as nearly as possible, to what extent the neoplasm has progressed. For this purpose a cystoscopic examination of the bladder is important. If the mucosa be found very edematous, or other evidence of inflammation be present, it is obvious that the neoplasm is approaching the bladder, and one must then be very careful in one's subsequent work. If the vagina be extensively infiltrated by the cancerous growth, it is inadvisable to do anything with the curette and the cautery.

I have had a specially heavy curette constructed for doing the scraping as expeditiously as possible. I have named it the "cancer spoon" to distinguish it from the smaller forms of spoons and curettes generally in use. Such a large instrument has an additional advantage; one is not so likely to perforate into the peritoneal cavity as with the ordinary small curette. All readily breaking-down structure is rapidly excavated with the spoon. The bleeding is stopped with an extra large dome-point electrode of a galvanocautery, so that it can be done more rapidly. To avoid burning the vulva and the vagina, I devised a speculum a few years ago which is constructed of metal and has a double hull, cooled by a continuous flow of cold water through the dividing space. In shape it is like the old style Ferguson speculum. The burning or charring is done very thoroughly, so as to leave practically only an outer shell of the uterus. The operation must be controlled by frequent examinations with the finger, lest we perforate the uterus and injure other structures. This has happened with me but once when using the cautery, though it occurred several times while doing the excavating with the style of spoons and curettes generally used. On these occasions I immediately ceased the operation, and no harm resulted. With the large spoon now used by me I have never broken through the uterus. It is well, now and then, to cool off the cavity which is being charred. This is easily done by putting ice shavings, or very small pieces of cracked ice, through the speculum, leaving them for a few minutes and then drying the surface before again applying the heat. Before the cooling speculum was devised I used vaginal retractors, wrapped with gauze wrung out in ice-water; yet this did not prevent occasional burns. With the cooling speculum, burns are entirely obviated.

After the eschar has been thrown off, it is best to use strong tincture of iodin in the cavity once every second day until the cavity has contracted. Or, judging from Gellhorn's experience with acetone, that remedy might be used with even greater benefit to the patient following the casting off of the eschar. Once I saw a fatal secondary result from the treatment. After the eschar was thrown off, a branch of the uterine artery began to bleed. I was called to see the woman in the middle of the night. The artery could be seen spurting. The cavity was tightly tamponed, but this did not stop the bleeding. By the time I saw the woman again, after returning home and preparing myself more energetically to control the hemorrhage, she had lost so much blood that she died of acute anemia. While it is asserted that patients have been cured by such treatment, I can not verify such results among patients observed by myself. I have seen, however, a number of patients whose lives were prolonged three years and more, and who were made comfortable for that period. It has been my custom to repeat the cauterization whenever necessary; i. e., when even a little bleeding showed itself, or if there was evidence of softening of the diseased uterine structure. I have recauterized some patients six times, and oftener, during three or four years.

A Paquelin cautery, a galvanocautery put in operation by a battery, or the old style "hot iron," are not so serviceable for this work as is the heating of the electrodes by the direct, or by the alternating current supplied for lighting purposes. I know of no method of treatment that will control the two symptoms, bleeding and offensive discharge, so satisfactorily as that of excavation and cautery.

The late Marion Sims used strong chlorid of zinc solution for this purpose. The objection to this procedure is that one can not know in advance how deep the destructive process of concentrated solutions of chlorid of zinc may go. In one instance that I have observed it went to such depth that the slough caused both a vesicovaginal fistula and a fecal fistula. It has been asserted that deep destructive action can be avoided by not allowing the tampon which is impregnated with the solution to remain for more than a day, or even for so long. I have found it very difficult to remove such a tampon until it has become loosened by the chlorid of zinc slough being ready to be cast off spontaneously. Indeed, I have found it impossible without causing so much traumatism to the underlying tissue that profuse bleeding must result. More important, however, is the question: If the full action of the medicament is not taken advantage of, why use it at all? Furthermore, despite the precautions that one may take by employing bicarbonate of soda, according to the directions laid down by Sims, I have never seen an instance in which the cauterizing effects of the zinc did not occur on parts other than those for which it was intended, and particularly in the vagina.

Carbid of calcium was also used on a number of patients many years ago, but, like other agents of supposed curative value, it proved a complete failure in my hands. Moreover, its caustic action is fully as intense on parts where it is not desired as is that of strong chlorid of zinc solution; and I know of no way to prevent this.

Several years ago, when the treatment of inoperable cancer with pyoktanin became known, through the late Mosetig-Moorhof, I used this remedy very extensively, and believed that, in some cases, I observed good results. A continuance of the observations made, however, proved my conclusions fallacious. Undoubtedly now and then a patient is benefited by the injections into the tumor, so far as the local condition is concerned, but the improvement is not permanent. This applies also to the injections with absolute alcohol, for which, for a short time, extravagant claims were made.

at intervals of from three to four hours in the last stages of the disease, if they were not more or less uremic.

In summing up, allow me to repeat that we must formulate a plan whereby we can teach women, not singly here and there, but in the mass, and in an ethical way, the insidiousness of the onset of cancer of the uterus; the necessity of consulting a physician on the first manifestation of any abnormal pelvic symptom; and the fallacy of the view that cancer occurs only at the climacteric period.

Physicians must accept the responsibility of letting no question in diagnosis remain unanswered. If they can not themselves make a positive diagnosis, they should ask aid of those who can.

THE PALLIATIVE TREATMENT OF CANCER OF THE UTERUS ESPECIALLY WITH THE THERMOCAUTERY *

WALTER B. CHASE, M.D.
Visiting Surgeon of the Bethany Deaconess Hospital; Consulting Gynecologist and Obstetrician to Long Island College Hospital; Consulting Gynecologist to the Nassau Hospital and to the Jamaica Hospital
BROOKLYN

As a preliminary to this paper I wish to state, in the most unequivocal terms, that the palliative treatment herein recommended is not advocated as a substitute for the early extirpation of the diseased structures by appropriate surgical procedure, but that it is applicable to cases in which the time has passed for such treatment, and also in certain cases in which the consent of the patient can not be obtained for early hysterectomy, who will accept a cautery operation as an alternative; neither is it my purpose to inquire into the etiology of the disease or review the literature of the subject, but to study it chiefly from the clinical point of view, with the reference to the one topic of palliation.

The prophylaxis of smallpox by vaccination, the curability of diphtheria by antitoxin, the relief of epidemic cerebrospinal meningitis by Flexner's serum, and the cure of certain cases of septicemia by antistreptococcus serum, have marked epochs in medical progress. Just at present the professional mind is focused on the preventability and curability of tuberculosis, with results which must count for a lessened mortality and increase in average longevity, with a corresponding freedom from avoidable invalidism and suffering.

The advocates of preventive medicine are engaged, in no small measure, in the efforts to discover the cause and cure of cancer; but the cause has so far escaped observation; and it is painfully evident that early radical measures have about reached the limit of their curative efficiency. It must be apparent, however, to the scientific and humane practitioner that the palliative treatment of uterine cancer is not receiving that attention which the subject demands, and it is to this aspect of the problem to which I ask your considerate hearing.

In 1903 I presented a paper on this subject to the American Association of Obstetricians and Gynecologists, while on previous and subsequent occasions I have called the attention of the profession to the appropriate treatment of these most unfortunate and neglected patients, and in what I shall say on this occasion I shall quote freely from that paper.

I count myself fortunate in presenting this topic for your consideration to-day, not alone from the distinguished character of this representative body, but for the larger opportunity it affords of reaching so great a number of the medical profession, in the hope that these suggestions will stimulate a renewed effort for the relief of a large class of unfortunate sufferers.

What I have to say will treat more of cancer of the cervix than of cancer of the body of the uterus, though in principle it applies to both. The specific indications for treatment will depend on the local involvement and the extent of tissue destruction; the end to be attained is to get rid of all diseased structures possible. When the disease has passed beyond the cervix, involving the bladder, the broad ligaments, and adjacent structures, it may be advisable to limit the treatment to the superficial area of ulceration. The cautery or caustic applications which result in opening into the bladder or rectum or which involve the pelvic viscera are to be avoided. The important problem is usually the exercise of that judgment which decides the conservative limit of approach and that skill which renders such effort availing.

After long personal observation and experience; I am convinced that no palliative treatment is at once so simple and effective as the thermocautery; and one advantage it has over all other methods resides in the fact that it effectively closes the lymphatic vessels, as is noticed in thermocautery operations elsewhere, notably in operations for hemorrhoids.

A well-equipped galvanocautery plant for hospital work leaves nothing to be desired; and as between a portable galvanocautery apparatus and a Paquelin cautery for non-hospital cases circumstance will decide. Those who attempt the operation with one apparatus will not infrequently regret another had not been supplied. Whether the superiority of the thermocautery over caustics is due to the influence of heat on the diseased cells beyond the area of cell destruction is a matter of opinion, but, in view of the better clinical results of the former, the deduction suggested is altogether logical and probable. To meet the varying indications a variety of platinum knives and electrodes are necessary.

I desire to give special emphasis to the fact that it is quite exceptional for the patient to suffer pain after the use of the thermocautery, provided, however, the mucocutaneous surfaces are not seared or burned. This requires tact and experience. I have usually found it easy to protect the vaginal surfaces from the injurious heat of the cautery by the use of strips of asbestos paper of proper size and shape. Where large areas of ulceration are present the curette may first be used to advantage. This is likely to result in pretty active hemorrhage. This bleeding is usually easily controlled by the application of pledgets of cotton applied with pressure, first dipped in dilute acetic acid, usually of half strength, or by the use of the adrenalin chlorid. After this, the cautery knife is to be applied at a dull red heat until the surfaces are thoroughly charred. The after-dressing consists of 5 per cent. iodoform gauze, reapplied daily, after cleaning the parts with liquor cresolis compositus or permanganate solution douches. The use of peroxid of hydrogen is likely to provoke hemorrhage.

To Dr. John Byrne, of Brooklyn, recently deceased, the professions are indebted to an elaboration of the correct use of the galvanocautery. His method of [illegible]tion in cancer of the cervix was to introduce, w[illegible] opera[illegible]o

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Some surgeons assert that the chemical destruction of the new growth is far superior to the destruction by means of a curette and cautery. I have made painstaking studies on this point, and am of the opinion that, if a patient is still in a condition for the application of such direct surgical methods as the curette and cautery operation, they afford the best palliative means at our disposal.

After cauterization has been completed, nothing further is necessary until the eschar begins to slough and excretions from the wound begin. Then the treatment with tincture of iodin, or with acetone, as advocated by Dr. Gellhorn, should be begun. After applying the iodin, it is best to put a tampon of absorbent cotton or sterile gauze into the cavity, so as to get it dry after treatment. The use of vaginal douches, so frequently employed to overcome discharge and to keep the patient clean, should be prohibited.

Gellhorn, of St. Louis, has published an article[4] which seems to be of value. He utilized the laboratory observations of the effect of acetone in a practical way on cancer of the uterus. He claims for it that it hardens the tissues. His method is as follows:

The new growth should be excavated as thoroughly as possible, and then the acetone applied through a Ferguson speculum. The pelvis should be elevated and the solution poured into the speculum. Care should be taken not to allow the acetone to come in contact with the external genitals. The surplus of acetone, after the remedy has remained in contact with the raw surface for from fifteen to thirty minutes should be absorbed with cotton. The treatment should be repeated every two or three days. Gellhorn maintains that this invariably relieves the patients of the main symptoms.

An analysis of the results with trypsin treatment does not seem to me to make it desirable to give trypsin a prominent place.

Fulguration is one of the latest therapeutic agents employed in the treatment of cancer. Czerny[5] asserts that if all the carcinomatous structure can be made accessible to fulguration the cancer may be cured, because fulguration does destroy the cancer cells. The "dose" of fulguration may be administered with exactness, and the treatment by the method is elective. With the patient under the influence of narcosis, fulguration may be applied for an hour, then the exposed cancer area may be excavated, and the wound surface again fulgurated for from ten to fifteen minutes. Wonderful therapeutic results are claimed for the treatment, which was first described by Keating Hart, of Marseilles.

As with all new remedies, one is apt to become overenthusiastic; I have so often been compelled to recede from an expressed opinion that I now believe it safer to test a remedy thoroughly before endorsing it.

This much we may say from accumulated experience: If in young persons with cancer beginning in the cervical canal the disease has perceptibly progressed beyond the line of so-called operability, life is not long to be enjoyed, no matter which of the palliative forms of treatment at present known to us is employed.

It may be that in the future a valuable therapeutic agent will be found in the ferments, judging from the results obtained by the injection of placenta ferment; but at present it is too early to be sanguine. This is said because we have been disappointed in every instance in which we were led to hope, from the claims made, that we had at last in our possession a remedy that would cure cancer of the uterus. I call attention only to a few of the more prominent ones: the Roentgen rays, radium, trypsin, etc.

The work of Professor Bier[6] is exceedingly interesting. Bier began his experiments—the injection of blood of a different species into malignant tumors—and published his investigations[7] in 1901. His object was to cause an artificial inflammation with an elevation of temperature and thus demonstrate that inflammation and fever were associated, especially so far as concerned the chemical process. He selected defibrinated blood from swine for his experiments, because hog's blood causes, when injected into cancerous, or into sarcomatous tumors, decided local and general manifestations. When 10 to 20 c.c. of such blood are subcutaneously injected, invariably, after the lapse of several hours, an inflammation is caused at the point of injection. This attains its maximum degree of severity in from one to three days. Then it gradually subsides. On repetition of the injection with such different blood the reaction is caused by a smaller quantity.

From lamb's blood, used by Bier in other diseases, a much milder reaction resulted. Never having observed any permanent ill effects from such injections, he believes them the safest method of producing fever and local inflammation. While the defibrinated blood does not contain leucocytes, these are supplied in abundance by the body of the recipient of the blood. Such blood does not seem to have any influence on normal tissues.

The action of the blood on tumors varies. Almost invariably, in suppurating carcinomata, the secretions are diminished. On existing pain, caused by the tumor, it does not seem to have marked influence. The growth of carcinomatous neoplasms is not noticeably influenced. The experiments are still being continued.

Though we know that women with inoperable carcinoma of the uterus have been kept alive for many years, apparently entirely cured, we can not be absolutely certain that there are not within the body some remaining cancer cells with latent avidity. I believe the recurrences after five years and more that have been reported from time to time may thus be explained. In other instances, it is likely that the diagnosis of carcinoma lacked verification under the microscope by a competent pathologist. To my personal knowledge, several such patients have been reported as cured by palliative treatment.

The pain that is caused by pressure of the tumor on nerves must be combated with narcotics. Of these, opium and its alkaloids are the only ones that give entire satisfaction. A number of substitutes have been proposed, with the assertion that they act equally well or even better; but none of them has stood the test. I do not hesitate to confess that I am an advocate of euthanasia in the case of such patients, if the giving of relief from pain by the administration of remedies that we are sure will give such relief can be so called. One should begin with as small a dose of morphin as is sufficient to relieve a patient, and then not repeat it oftener than necessary. The dose must be increased later, and the intervals of administration shortened. I have had patients who required five grains of morphin at intervals of from three to four hours in the last stages of the disease, if they were not more or less uremic.

THE PALLIATIVE TREATMENT OF CANCER OF THE UTERUS ESPECIALLY WITH THE THERMOCAUTERY *

WALTER B. CHASE, M.D.
Visiting Surgeon of the Bethany Deaconess Hospital; Consulting Gynecologist and Obstetrician to Long Island College Hospital; Consulting Gynecologist to the Nassau Hospital and to the Jamaica Hospital
BROOKLYN

As a preliminary to this paper I wish to state, in the most unequivocal terms, that the palliative treatment herein recommended is not advocated as a substitute for the early extirpation of the diseased structures by appropriate surgical procedure, but that it is applicable to cases in which the time has passed for such treatment, and also in certain cases in which the consent of the patient can not be obtained for early hysterectomy, who will accept a cautery operation as an alternative; neither is it my purpose to inquire into the etiology of the disease or review the literature of the subject, but to study it chiefly from the clinical point of view, with the reference to the one topic of palliation.

The prophylaxis of smallpox by vaccination, the curability of diphtheria by antitoxin, the relief of epidemic cerebrospinal meningitis by Flexner's serum, and the cure of certain cases of septicemia by antistreptococcus serum, have marked epochs in medical progress. Just at present the professional mind is focused on the preventability and curability of tuberculosis, with results which must count for a lessened mortality and increase in average longevity, with a corresponding freedom from avoidable invalidism and suffering.

The advocates of preventive medicine are engaged, in no small measure, in the efforts to discover the cause and cure of cancer; but the cause has so far escaped observation; and it is painfully evident that early radical measures have about reached the limit of their curative efficiency. It must be apparent, however, to the scientific and humane practitioner that the palliative treatment of uterine cancer is not receiving that attention which the subject demands, and it is to this aspect of the problem to which I ask your considerate hearing.

In 1903 I presented a paper on this subject to the American Association of Obstetricians and Gynecologists, while on previous and subsequent occasions I have called the attention of the profession to the appropriate treatment of these most unfortunate and neglected patients, and in what I shall say on this occasion I shall quote freely from that paper.

I count myself fortunate in presenting this topic for your consideration to-day, not alone from the distinguished character of this representative body, but for the larger opportunity it affords of reaching so great a number of the medical profession, in the hope that these suggestions will stimulate a renewed effort for the relief of a large class of unfortunate sufferers.

What I have to say will treat more of cancer of the cervix than of cancer of the body of the uterus, though in principle it applies to both. The specific indications for treatment will depend on the local involvement and the extent of tissue destruction; the end to be attained is to get rid of all diseased structures possible. When the disease has passed beyond the cervix, involving the bladder, the broad ligaments, and adjacent structures, it may be advisable to limit the treatment to the superficial area of ulceration. The cautery or caustic applications which result in opening into the bladder or rectum or which involve the pelvic viscera are to be avoided. The important problem is usually the exercise of that judgment which decides the conservative limit of approach and that skill which renders such effort availing.

After long personal observation and experience, I am convinced that no palliative treatment is at once so simple and effective as the thermocautery; and one advantage it has over all other methods resides in the fact that it effectively closes the lymphatic vessels, as is noticed in thermocautery operations elsewhere, notably in operations for hemorrhoids.

A well-equipped galvanocautery plant for hospital work leaves nothing to be desired; and as between a portable galvanocautery apparatus and a Paquelin cautery for non-hospital cases circumstance will decide. Those who attempt the operation with one apparatus will not infrequently regret another had not been supplied. Whether the superiority of the thermocautery over caustics is due to the influence of heat on the diseased cells beyond the area of cell destruction is a matter of opinion, but, in view of the better clinical results of the former, the deduction suggested is altogether logical and probable. To meet the varying indications a variety of platinum knives and electrodes are necessary.

I desire to give special emphasis to the fact that it is quite exceptional for the patient to suffer pain after the use of the thermocautery, provided, however, the mucocutaneous surfaces are not seared or burned. This requires tact and experience. I have usually found it easy to protect the vaginal surfaces from the injurious heat of the cautery by the use of strips of asbestos paper of proper size and shape. Where large areas of ulceration are present the curette may first be used to advantage. This is likely to result in pretty active hemorrhage. This bleeding is usually easily controlled by the application of pledgets of cotton applied with pressure, first dipped in dilute acetic acid, usually of half strength, or by the use of the adrenalin chlorid. After this, the cautery knife is to be applied at a dull red heat until the surfaces are thoroughly charred. The after-dressing consists of 5 per cent. iodoform gauze, reapplied daily, after cleaning the parts with liquor cresolis compositus or permanganate solution douches. The use of peroxid of hydrogen is likely to provoke hemorrhage.

To Dr. John Byrne, of Brooklyn, recently deceased, the professions are indebted to an elaboration of the correct use of the galvanocautery. His method of [illegible]tion in cancer of the cervix was to introduce, w[illegible] opera[illegible]

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

the cervical canal, an expanding double tenaculum forceps that when opened held so firmly that any practical degree of traction could be made. A circular fissure, close to the vaginal junction, was then made for the reception of a platinum wire loop. By continued traction while this wire was slowly eating its way through the structures the entire cervix was removed. His next step was to use a sharp curette within the whole area of the uterine cavity. This afforded sufficient space for the introduction of another electrode, having a larger cauterizing surface, going over this entire surface. The cavity was then sponged dry and a tampon soaked in acetic acid and tannin applied, and the parts made dry; after which a dome-shaped cautery instrument brought to a cherry-red heat was slowly applied to this whole area until the parts were completely charred and black. By proper application of this thermocautery nearly the entire uterine structure is destroyed, save a shell of tissue and the peritoneal covering.

It was by his skill and persistency that the efficacy of the galvanocautery was established on a solid basis. The skill in the use of the thermocautery was, first, in not going far beyond the area of involvement, and, second, in having the cautery knife hot enough to burn the structures and not hot enough to disintegrate them too rapidly. If the proper heat is not maintained, troublesome hemorrhage may follow. I have seen patients far advanced with cancer of the cervix and uterine body, showing signs of grave systemic infection, who lost their cachectic appearance after thermocautery operations.

The primary objection to the powerful escharotics like mineral acids, caustic potash, etc., is the difficulty, if not the impossibility, of gauging their corrosive action, the pain of which is often atrocious and far greater than that of the thermocautery.

Daily vaginal douches with permanganate of potassium or compound solution of cresol are the best antiseptics. In all manipulations of the parts subsequent to the operation the greatest gentleness should be observed. Generally the use of bivalve speculum should be avoided, as it is likely to impinge on this area. Usually the dressing is best accomplished by having the patient in the Sims position and by using a medium-sized or small Sims speculum. Mention should be made of the utility of oxid of zinc, carbolized, or iodoform gauze. The slough separates usually in from one to two weeks. Daily dressing must be faithfully applied every day until healing follows, or, should it not follow, its use must be continued to keep the parts as aseptic as possible. Where healing is imperfect, and unhealthy granulations reappear, they may be touched with carbolic acid or silver nitrate, pure or diluted as the case may indicate. As in granular surfaces, generally the recognized healing power of silver nitrate must not be forgotten.

In cases in which healing does not follow, or in which the disease returns, the acrid discharge is a prominent factor in the production of pain, and it goes without saying that local cleanliness and disinfection are constantly required.

In hopeless cases this local treatment is a *sine qua non* for the patient's comfort; and it is at this point in the history of many patients that the failure to give relief occurs. It is possible in some instances to train an intelligent nurse to do the dressing, but the skilled hand of the attending physician is most satisfactory. It takes time and patience, but the careful expenditure of both gives the largest degree of comfort and the pain is reduced to the minimum. Sometimes the patient experiences much relief from the local use of cocain, frequently repeated. Not infrequently rectal suppositories containing two grains or more of codein and three of extract of hyoscyamus add materially to the relief of the pain. Later on morphin sulphate in increasing doses may be required to minimize suffering. If this is not well borne the deodorized tincture of opium may be substituted. Again I reiterate the necessity of constant cleansing of the parts, by skilled hands, as indispensable to greatest relief from suffering.

I can not speak from the magnitude of experience which Dr. Byrne presented in his paper to the American Gynecological Society several years ago, in which he stated that he had never known a recurrence of the disease at the part from which it had been thus removed, but that it had reappeared in the fundus, ovaries, or some adjacent structure. In this I have not been so fortunate, owing perhaps to technic less perfect than his. By this method in the report referred to Dr. Byrne operated on 367 patients with cancer of the uterus, of whom at the end of five years 19 per cent. were still alive. This is the most remarkable, as he operated in every case which presented itself, without a single primary mortality. Taking this fact into account, his statistics show most remarkable results, for probably the statistics of no other operator include the cases of so-called inoperable cancer.

The conjecture—well founded in regard to some later ones—that statistics are too often a medium for personal exploitation rather than a scientific record of actual events in support of their authors' declarations, can not be entertained by those who knew Dr. Byrne personally, in regard to his statistics, which are open to no such suspicion or doubt, and are entitled to the confidence of the profession.

There is, it should be mentioned, no reason why in recurrent cases the thermocautery can not be repeatedly applied with benefit. It should be mentioned that at the time these several cases reported came under observation the disease was so far advanced as to leave no doubt of its malignancy.

I regret that want of time prevents more than passing notice of the utility of *x*-ray and radium treatment in uterine cancer. My use of either has not been sufficiently extensive to enable me to speak authoritatively as to their value. So far as my experience goes I regard the radium as far the more useful, in that granulating surfaces take on more healthful activity after its use than that which follows the use of the *x*-ray, and this is, I believe, in keeping with the recent observations. As illustrative of the results of palliative treatment I report briefly the following cases:

Case 1.—The patient, a married woman, aged 43, entered the Skene Sanitarium, in March, 1901, with a cauliflower excrescence of the cervix as large as a man's fist. She had had numerous conceptions, all of which terminated in miscarriage; but as these were intentionally procured there was a well-grounded suspicion that her disease was related to the incident traumatism. This growth was reflected on the vaginal wall anteroposteriorly and laterally, which forbade a primary effort at hysterectomy. On March 14 I removed the growth by the galvanocautery and amputated the cervix at the vaginal junction. The surfaces healed kindly, save a small area on the uterine stump about the size of a silver half-dollar. On May 21, following, the patient re-entered the sanitarium and I performed an abdominal hysterectomy. Prior to this operation she was weak, anemic and in poor physical condition. Her convalescence was satisfactory. She was kept under monthly observation by her physician, and in May, 1902, a year later, there appeared at the seat of the vaginal cicatrix a nodular mass rather larger than a silver twenty-five-cent piece. At this time she entered the Memorial Hospital and I removed a button of structure, opening from the vagina into the peritoneal cavity, the size of a silver half dollar. I examined her during the past year and she is in perfect health, with no sign of the return of the growth.

Case 2.—The patient, a married woman, aged 46, German, multipara, dated her trouble to a miscarriage seventeen years previously. She had a large, bleeding, ulcerating cauliflower excrescence of the cervix, extending to the vaginal walls, which nearly filled the vagina. The discharge was offensive and the patient's health was seriously impaired from the frequent hemorrhages, associated with marked cachexia. She entered the Memorial Hospital Sept. 23, 1902, and on the 25th I removed the entire growth by the thermocautery. In two months' time it had healed under daily dressings, save for a cup-shaped cavity three-quarters of an inch in diameter and one-half inch deep. The patient's general health was greatly improved. Owing to non-healing she had two more thermocautery operations in November, 1902, and June, 1903. In November, 1903, the disease having made some progress without materially affecting the patient's general health, Roentgen ray apparatus was installed in the home and on every second or third day for nearly three months treatment was given. This was followed by the use of radium and the ulcerative process was greatly retarded, and the patients general health fairly maintained with but slight pain, up to the time of her death, May 7, 1904. For several weeks previous to her death the normal anatomic relations between the vagina, bladder and rectum were altogether lost and the amount of gauze daily used to fill this cavity amounted to many yards. During the twenty-one months of attendance the patient was visited by myself or my assistants about 750 times. It is at once apparent that such attention is most exacting in its demands on the attendant, but it demonstrated the fact that almost entire freedom from pain was the result, and that it was worth all it cost.

Case 3.—The patient, a married woman, German, multipara, entered the Memorial Hospital in September, 1902, with carcinoma of the cervix. The typical symptoms of malignancy were in evidence. I did a high thermocautery operation, entering well up into the uterine cavity, which was unexpectedly followed by prompt healing. About four years ago the patient was in excellent health locally and generally; since that time I have lost track of her owing to the absence of her physician, Dr. Frederick A. Cook.

Case 4.—During March, 1896, a married woman, multipara, aged 42, came under my observation with typical cancer of the cervix, accompanied with extensive involvement. Hemorrhage was violent and the patient was cachectic. She was greatly exsanguinated and very weak. She entered St. John's Hospital in March, and I did a high galvanocautery amputation as soon as her health permitted. She made a slow but satisfactory recovery, as far as the healing and local symptoms were concerned, and after two or three months she was able to resume her family duties. In November of the same year she entered the Bushwick Hospital for extirpation of a large gland of Bartholin. At this time there was no sign of return of the cancerous growth. On June 16, 1897, she re-entered the Bushwick Hospital, being seven months pregnant. The disease had returned, springing up around the old stump. After watching its behavior, I feared, from the hardening and infiltration of the uterine and contiguous structures, labor might induce rupture of the uterus, and on July 18, at the eighth month of pregnancy, I removed the diseased growth, which encircled the uterine outlet, by the thermocautery. No shock followed and the patient was delivered of a healthy living child on August 6. Her convalescence from the confinement was satisfactory, as was the healing after the cautery. She enjoyed good health for nearly a year. Then the growth reappeared and she entered the Central Hospital, June 21, 1898, and I removed as far as possible the cancerous mass which had returned. She returned home August 25. The healing was not satisfactory and she died a few weeks later from cerebral embolism, which only anticipated the inevitable results of her condition.

In the cases reported, ultimate recovery from the disease was not expected, and no promise of cure was held out to the patients. Patients 1 and 3, after periods from four to eight years, according to accepted standards, were cured. Patients 2 and 4 were greatly benefited and their lives were prolonged for years with very little suffering—a result unattainable so far as I know by any other method of treatment.

In view of these results, I appeal to the members of this Association, and to the medical profession everywhere, not to allow these cases of so-called inoperable cancer to go on without an honest effort to afford relief by the means herein recommended; these efforts will, I am convinced, be appreciated alike by the sufferer and her friends, will give the physician the sense of obligation and duty discharged, and perchance save some life to happiness and usefulness.

1050 Park Place.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BOLDT AND CHASE

Dr. G. Betton Massey, Philadelphia: I hope that within five years, as the undesirability of stimulating cancer tissue by traumatism is fully appreciated, we will see the end of cutting into the tissue itself, whether by the sharp curette or the knife. I protest against the curette in living cancer tissue as productive of regional and distant metastases. The tributes to the late Dr. Byrne in the papers on the thermocautery are pleasing and indicate progress in the right direction. While the thermocautery in cancer of the cervix represents improvement on previous procedures there are three practical objections to it: 1. The difficulty in avoiding accidental burning of the vagina. 2. The difficulty in maintaining a sufficiently high heat at the tip of the instrument. The loop must be heavy and the chances are that most of the heat is expended at the proximal end of the loop rather than at the tip, where the disease is most virulent, thus rendering the destruction of the actively-growing periphery uncertain. 3. The third objection is the horrible odor emanating from the slough during its separation, compared with the slight odor from sloughs produced by the electrosurgical use of zinc mercury ions. All these difficulties are avoided by the use of the electrochemical method, the technical details of which may be briefly stated as follows: With the patient in either the dorsal or Sims' position, and reclining on a large, moist kaolin pad, slender zinc needles of sufficient length and insulated to within 2 cm. of the tip are amalgamated and inserted in the diseased tissue and a current of 100 milliamperes turned on and maintained for thirty minutes. As the zinc-mercury points are connected with the positive pole the tips are dissolved and the two metals, in the form of ions, are driven into chemical combination, with the cancerous tissue, devitalizing and sterilizing it. The applications are repeated daily, being well-borne without anesthesia other than a possible dose of morphin, until a total current of 1,000 milliamperes has been employed for an hour, or the tissue seems free of the living growth, when they are intermitted for three or four weeks to permit the sloughs to separate. The best results are secured in the earliest cases, and in patients who are carefully watched for years afterwards and replaced under the method on the slightest evidence of abnormal conditions.

Dr. J. H. Carstens, Detroit: The only difference virtually between my treatment and that of Dr. Chase is that I do not, as a rule, use the galvanocautery, but use chlorid of zinc, which I think accomplishes identically the same results. I teach the general practitioner, especially the practitioner from the country, to watch these cases, examine them every two or three weeks, and on the appearance of a little raw spot and the recurrence of the growth, it may be only the size of a pea, to remove it immediately and put in a wad of cotton with a saturated solution of zinc chlorid so that it will be cauterized, and this should be repeated when necessary. Of course, the cancer that is inside and is not ulcerated does not produce the serious results that we get from the ulcerated condition. The physician curettes thoroughly, cleans and cauterizes, or uses the *x*-ray, and the woman thinks for six months that she is well. Then there will be recurrence. Last year at the meeting of the Michigan State Medical Society I read a paper urging that a circular be issued by the state board of health on what women in the "cancer age" should know about cancer. A few of the things suggested were that a woman who was flowing more than usual was in a suspicious condition; that a woman who had a discharge at that time was in need of examination; that a woman who had a discharge which became irritating ought to be thoroughly examined. The circular should be small, just about ten lines. It must be short, otherwise, women will not read it. The State Board of Health has agreed to issue such a circular. It will be furnished to all the county societies so that all the physicians can distribute them. I furthermore suggested that cancer be taken up in the same way as has tuberculosis; and that every year, on a certain day in the year, there be what may be called "cancer day," when the people shall talk about cancer, and the symptoms of cancer, and every paper in the state shall publish an article on cancer. In this way I believe women would be led to consult their physicians before the condition was past hope.

Dr. C. C. Frederick, Buffalo: I have had some experiences which have been very satisfactory and which lead me to emphasize the points brought out by Dr. Boldt and Dr. Chase in the effort to stimulate general practitioners to make an effort at palliative treatment in inoperable cases of cancer of the uterus, and with the idea of lengthening the days and of securing some comfort for these poor unfortunates. I believe that no cancer of the cervix which has gone beyond the limits of the body of the uterus ought to be subjected to attempts at radical removal because it is futile. But the use of the curette and the cautery does do a great deal for these patients and some of them are cured. The patients will get rid of the infection which occurs; their appetites will improve, the anemia disappear, and for a time they will think they are well, and then they will go down again. To prevent them going down so rapidly the curette and cautery should be used every two or three months. In other words, the patient should be watched and the treatment repeated. I have two patients whom I consider cured. In one, a woman with inoperable cancer of the cervix, the disease occurred twelve years ago. I opened the abdomen with the idea of removing the uterus, but found that there was involvement at the vesicoperitoneal fold, and as she had been bleeding a good deal I tied both uterine arteries and closed the abdomen. I scraped out the cervix and used a cautery. She recovered, and to my astonishment that woman is living to-day. There is a hard cicatricial mass present, but she says that she is absolutely well. I cauterized her only once. What the cautery did and the tying off of the arteries in conjunction with the cautery I do not know. I suppose there was a diminution of the blood supply preventing the further growth of the carcinoma. I have another patient, treated similarly, minus tying the uterine arteries, four years ago last September. I cauterized and curetted the woman four times in the course of the year. The cervix contracted and later I did a total hysterectomy and she is perfectly well to-day. I have four other patients in whom I have done the same thing. The process of constriction due to the cautery, the scar tissue contracting and inhibiting the growth of the cancer cells render it possible often times at a later time to take out the uterus and make a clean operation with the chance of recovery.

Dr. Henry O. Marcy, Boston: I have one criticism to make of Dr. Boldt's instrument; it does not give the hand room. Many years ago I found in curetting that in leaving a piece of cotton about the area and applying the thermocautery, steam was generated in a considerable degree and from that day on my colleagues and I have used a considerable amount of wet cotton packed above and below and we find that the steam thus generated penetrates the connective tissue deeper than the cautery itself and yet does not destroy the vitality of the structure. I believe that we can do a great deal in the palliative treatment of cancer.

Dr. John A. McGlinn, Philadelphia: I think the first part of Dr. Boldt's paper in reference to the necessity of early diagnosis is of special importance. If we fully realized just what this cancer problem means, probably we would be more alive to the necessity of waging an active campaign of education among the profession and laity for the early recognition of the disease. With our present knowledge our sole hope of combating the evil lies in its early recognition. That cancer is on the increase is beyond question. In the decade from 1890 to 1900 it showed, in the registration area, an increase of 12.1 per 100,000 population. Statistics show that it has increased in this area from 53 per 100,000 population in 1890 to 70.8 in 1906. Williams has shown that in England one woman out of eight past the age of 35 dies of cancer. In a recent paper I have shown that in the registration area one woman out of eleven at all ages dies of cancer and past the age of 35 one woman out of nine will die of the disease. The age of greatest frequency is between 50 and 54, when one man in fourteen and one woman in five die of cancer. In the registration area in 1906, had cancer been cured, there would have been a total saving of life of 373,574 years, or a total saving of earning capacity of $224,144,400, enough to endow for all time laboratories and clinics of research which would eventually solve this most important problem of public health. In many parts of Pennsylvania the cancer death rate now exceeds that of tuberculosis. I have shown that if the present increase of cancer death rate and decrease of tuberculosis be maintained the foul plague will displace the white plague as the great curse of mankind by the years 1931. Practically one-third of all deaths due to surgical conditions are caused by cancer. When we realize that the uterus is the site in 27.68 per cent. of all cases of cancer in women, as gynecologists, we know that there is a splendid field for our endeavors. If such measures as Dr. Carstens suggested were adopted much could be done to eradicate this evil. As teachers we should remember that the profession needs to be educated in the need of early diagnosis just as much as the public.

Dr. I. S. Stone, Washington, D. C.: I am not going to discuss the question in its broadest sense. Twenty-five years ago Dr. Bryne taught us the application of the cautery in the treatment of cancer of the uterus and Dr. Van de Walker how to use the chlorid of zinc for the same disease, and I believe we have learned very little since that time. Dr. Smith, of the United States Fish Commission, has recently told me of something which may at some time in the near future be announced from one of the laboratories of the United States making a study of cancer. In a certain lake there have been observed innumerable fish with cancer of the thyroid gland. That at first thought seems a little thing, but there is an association of cause and effect right there which these men are undertaking to sift to the bottom by transplanting the disease into other fish. We have always had a hope that the proof would come of the parasitic nature of the disease. Of course, I know nothing about the project personally or experimentally, but I think that this little ray of hope is something which may give us encouragement and I want every one to believe that we will yet be able not only to teach concerning the danger of cancer, but that we shall eventually find a cure.

Dr. Howard A. Kelly, Baltimore: There are only two or three ways by which we can get around this cancer problem. One is by discovering the cause, and I hope we shall learn something from the work mentioned by Dr. Stone. Another method is by more radical operation. I feel that we have gone to the limit there. Another method is to get at the disease in an early stage. We ought to bend all our efforts to attacking the subject on that side. I would suggest circularizing the public and that we should not be too afraid of talking about these things in the public press. We talk a good deal about tuberculosis. This is a little more recondite, but when we have an enemy to face we have to bring him out in the open. We are entirely too reticent about telling reporters what they want to know, and in this way disseminating the information which will guide the people. One more suggestion is that every woman who has borne a child should be examined at least once a year from her thirtieth to fiftieth year. If this were done we would find the cases which to-day are coming to us too late to be helped. I use curettage and cauterization in these cases, but have a little different method from the one in general use. Dr. Spencer Brown, of Montclair, N. J., told me of the method of surrounding the parts with asbestos. When you get deep into the disease, instead of continually burning the area, use the asbestos around one of the electrodes; do not touch the disease, but hold the cautery while it cooks the tissues. Hold it at one place for three, four or five minutes, and then move it to another point. You will find this a very satisfactory and effective way of using the cautery.

Dr. John Osborn Polak, Brooklyn: In cases which seem beyond the reach of radical surgical procedure, the disease may sometimes be completely extirpated by the cautery. By the use of Byrne's divulsing tenaculum the uterus may be drawn into a large, yet short, Ferguson speculum, and the entire body of the uterus burned out with the cautery, leaving only the peritoneal shell. I know several women who are living from six to ten years after this treatment, who were beyond the reach of radical operation at the time they presented themselves. To make this procedure successful, sufficient time must be taken carefully to char every surface, and to permit the slow radiation of heat. Great credit should be given to the memory of Dr. Byrne for all he did for cancer, and those of us who have lived within the radius of his work can testify to the high character of it.

Dr. Emil Novak, Baltimore: The question of educating the public in the crusade against cancer is one of the greatest importance. I think that in the life-history of cancer we can recognize several stages: (1) From the beginning of the cancer until the woman first observes symptoms; (2) from this period until she brings her symptoms to the attention of the physician; (3) the period between the time she calls the attention of the general practitioner to her symptoms to the time they are brought to the attention of the gynecologist; (4) from the latter period until the operation is performed. These stages are all of variable length, as we all know. Very few men will hold that the surgeon himself is often culpable in delaying operation on cancer. I think that all of us realize that the general practitioner is frequently to be blamed for tardiness in bringing the cancer patient to operation, and that the patient herself is even more frequently to be blamed for allowing her symptoms to go on until she is in a hopeless condition. The only aspect of this general problem on which I wish to speak is the rôle played by the ignorance of the patient and the point already made by Dr. Carstens and Dr. Kelly on the value of circularizing the public. I have had some little experience in trying to educate the public along medical lines, not only concerning cancer, but on general hygiene. In Maryland, we have an almost perfect system of public instruction in medical matters, carried on by means of public lectures, along the same lines followed out at the Harvard Medical School, also by a system of minor lectures to organizations of various kinds, and finally, in a rather novel way—by means of the newspapers. The two largest newspapers in the state have joined hands with us, and we issue a weekly "health bulletin" in which topics of interest to the public are discussed by authorities on these subjects. The articles are not signed, but are simply labeled as being issued under the auspices of the state medical organization. Week by week both newspapers publish identically the same articles, and they have done a great deal of good. Among other things, we have discussed cancer, and although we realize that the newspapers offer the best medium for reaching the public, we have also come to realize that we cannot do as much with the newspapers against cancer of the uterus as against other diseases. Newspapers which do not hesitate to publish advertisements of "female regulators," etc., assume a very bizarre modesty in discussing such subjects as cancer of the uterus in their reading matter. I think Dr. Kelly is right in saying that from the standpoint of cancer of the uterus we must for the present rely mostly on pamphlets. In this way we will educate the public and the public will educate the newspapers. We want to create first of all a good healthful public sentiment. People die of cancer because they do not realize the significance of the early symptoms. Ignorance is the fundamental obstacle in attacking the question of cancer, and we must save the people, not from their own folly, but from their own ignorance.

Dr. H. G. Wetherill, Denver: I want to call the attention of the Section to a little device which is very useful for other purposes and which Dr. Kelly's suggestion leads me to think might be applied to this particular use. The instrument is what is known as a "blender" in a pyrography outfit; a platinum point, such as is used in making burnt-wood pictures, having an opening in the end. A stream of hot air passes through the hole in the point and without touching the surface with the point the tissues may be cooked or cauterized to any desired degree. I see no reason why it should not work within the speculum as Dr. Kelly has suggested. We now know that primarily cancer is a local disease and that the successful treatment of cancer hinges on its early diagnosis. When we devise some means by which an early diagnosis may be made, then the results of the treatment of cancer may be improved. In the discussion on another paper the statement was made that there was no relation between fibroid tumors and carcinoma. We often find an association of fibroid tumors and carcinoma, but rarely find a true carcinoma originating in a uterine fibroid, and one sometimes sees uterine carcinoma which has not invaded an existing fibroid growth, but has skirted or circumscribed it. In some instances, however, fibroid tumors may cause carcinoma of the opposite wall of the uterus from pressure and irritation. We have that phase of fibroid tumors to think of in the consideration of this question.

Dr. H. J. Boldt, New York: The point has been this: All the talking that we do without some action is not going to be of benefit. I wish a committee might be appointed from this Section to formulate a set of resolutions in regard to the education of women concerning cancer. We will then get some results in the matter of early diagnosis. In the application of the galvanocautery a portable battery will not give a continuous heat sufficiently long, but if we have the direct or the alternating current, there is absolutely no trouble in getting enough heat. The prevention of burns has interested me very much. I have tried the different devices and find them all useless compared with the cooling speculum which I have shown. We may use any degree of heat and as long as desired without burning the vulva, or any part of the vagina on which we do not want the action of the heat. I have cauterized a large number of patients; furthermore, there is plenty of room to work through the speculum. The best form of treatment at the present time is enucleation with a sharp spoon, provided the disease has not advanced too far. Leopold has done considerable experimental work on animals, rats and mice; similar experimentation as is done in Buffalo. The important point is the early diagnosis. I hope some one will make a motion to the effect that the chairman appoint a committee from this Section to present resolutions to the main body, who shall communicate such resolutions to the public at large. The fact should be emphasized that cancer is not limited to any particular time of life. Women should be instructed to apply to their physicians at once on the first manifestation of any abnormal pelvic symptoms. Then if the physician does not feel himself competent, or if there is any question as to the diagnosis, he should endeavor to have some one help him in the case.

Dr. W. B. Chase, Brooklyn: I am entirely in accord with the sentiments expressed by Dr. Boldt and the others regarding prevention. Dr. Polak was mistaken in the fact that reference was not made to Dr. Byrne's thermocautery methods of treating cancer of the cervix. I believe that the pain of cauterization is far greater than the majority of physicians believe it to be. In fact, as I know, the pain is so great that it is very serious; whereas, the after influence of thermocautery is practically painless. If the cutaneous surfaces are not burnt the subsequent pain is practically *nil*. I congratulate the Section that evidences of cure of certain cases of carcinomatous disease of the uterus, even when the treatment is undertaken as palliative, are coming to our notice. It certainly ought to be encouraging to every one of us not to forsake a case simply because we believe it to be hopeless. We have struck the keynote of the whole situation when we ask that knowledge regarding early successful treatment be disseminated, not only among the profession, but among the laity, the sooner will the mortality diminish. While we are doing all we can to disseminate information, it behooves us as physicians and surgeons that we do not forget suffering womanhood, and that we continue as best we may to meet the indications for relief of these sufferers.

THE ANALGETIC EFFECT OF LOCAL APPLICATIONS OF SOLUTIONS OF MAGNESIUM SULPHATE AND OTHER SALTS

PRELIMINARY NOTE *

SOLOMON SOLIS COHEN, M.D.
PHILADELPHIA

In certain cases of cutaneous inflammation, arthritis, etc., in which I was led to make observations on the effects of external applications of magnesium sulphate, certain deep-seated pains independent of the particular affection of which a patient complained, apparently disappeared in sequence—I do not say in consequence, but in sequence—of the application. In order to test whether or not this was a psychic phenomenon, other applications were made—simple saline solution, distilled water, magnesium chlorid, sodium sulphate, etc.; and, while any moist dressing in these particular cases (I am not referring now to cases in general) seemed to diminish the pain somewhat, none of them had the same decided effect as the magnesium sulphate. The nearest in such power was sodium sulphate.

As to classes of cases: One was an aneurism. A man suffering from thoracic aneurism with projection of the chest wall had some slight cutaneous irritation over the mass—I have forgotten its cause. Application of magnesium sulphate solution was made. The relief to his deep pain was so great that he asked to have the dressing repeated after the irritation had subsided. This apparently was a psychic reaction; yet when the application was changed to sodium chlorid solution without the man's knowledge it failed to produce the same effect. But magnesium citrate likewise failed. The effect was not lasting and the application had to be repeated from time to time, and finally in this particular instance of aneurism it failed to have any further effect. Other cases in which this apparently reflex analgesia was observed were cases of gastric ulcer, gastric carcinoma, lymphatic leukemia, acute pericarditis, sciatica, headache of unknown origin, chronic pleurisy. In many instances it failed completely. To determine whether in any case there was any local anesthesia produced, tactile sense, pain sense, thermal sense, etc., were tested in normal persons, in the patients relieved by magnesium sulphate, and in the patients not relieved by it. In no instance was any effect of any kind on the cutaneous sensation detected, whether the examinations were made within ten minutes or after thirty minutes to an hour. I present this merely as a curiosity of observation. The measure may be useful at times when one does not care to give morphin in cases of deep-seated pains, acute or chronic.

The problem is complicated and the method of observation is inexact, so that I am not now prepared to say that there was a definite chemical or pharmacologic action of the magnesium sulphate in these cases. The matter seems, however, to be worth proving further.

1525 Walnut Street.

ABSTRACT OF DISCUSSION

Dr. Reid Hunt, Washington, D. C.: Dr. S. J. Meltzer, New York, did some experiments on animals in such a way that the psychic element could be completely *eliminated*. The remarkable results shown seem to be good reasons for believing that magnesium sulphate will relieve pain materially. Dr. Meltzer anesthetized a rabbit and while the animal was deeply anesthetized placed both ears in hot water for a very short time and then the right ear was treated with a strong solution of magnesium sulphate and the left ear with an isotonic solution of some other salt. Some little time afterward, the ear treated with magnesium sulphate was upright and seemed normal, the ear treated with salts of the same concentration was drooping and evidently not on the road to recovery. Later, the ear treated with magnesium sulphate was practically normal, only a few small ulcers being present; the other ear, treated with other salts had largely sloughed away. Dr. Meltzer suggested treating burns with magnesium sulphate. It has been used to some extent for burns of the first and second degree and has given much relief and evidently aided greatly in healing.

Dr. Theodore Potter, Indianapolis: Do the members of this Section use the solution of magnesium sulphate in erysipelas? It is coming to be talked about recently and in some localities is rapidly supplanting the application of various other medicaments like ichthyol. We run from one thing to another and at present we run toward sulphate of magnesium. I have used it in a few cases of erysipelas, perhaps it has done as much good as cold water, which thus far seems to do as much good as anything. It appears that this drug will supplant other things rapidly, such as ichthyol, once widely used, *and in which the profession has largely lost confidence.*

Dr. Solomon Solis Cohen, Philadelphia: I am, fortunately, or unfortunately, of that mental temperament which cannot always make an unqualified statement. I remember very well that my honored teacher of therapeutics used to be very positive concerning each particular drug that he was lecturing about, that it would "cure" many and various affections. All I am able to say of this or any drug is that it is useful under certain limitations. Magnesium sulphate, applied locally, in certain cases of erysipelas, is useful. But there are cases of intense, *rapidly spreading and erysipelatous inflammation,* with toxic systemic symptoms, in which I should be very reluctant to depend on the external application of Epsom salt as being all that medical science could do for the relief of the *patient. In mild cases of strictly localized erysipelas, without* much toxemia, a dressing of cold, saturated magnesium-sulphate solution, properly applied, seems to be about as useful as, and perhaps a little more useful than, anything else that I have used. It is not so dirty as ichthyol and seems to afford the patient a great deal of comfort. It relieves the burning especially. I don't know that it checks the spread of the local infection, but it does relieve, to a marked degree, the local distress. It may confidently be used for such purposes, but it should not be used for the things that it will not do. I may add that I sometimes say to my students, and I think it may be said to physicians, while an elephant cannot climb a tree, yet an elephant is a very useful animal for heavy draught purposes. So with our drugs. Magnesium sulphate in the case of erysipelas may climb a tree; but it is not to be depended on for heavy draught.

Physical Strain on Soldiers.—The British Army Annual for 1909 asserts that smartness of drill often causes unnecessary heart strain. "The position of attention is most injurious to the health of the soldier, and far too much of his time is passed in that attitude. The movements of respiration are seriously checked in the effort to keep the chest expanded. After a time the chest walls become more or less fixed in a position of expansion, and the range of expansion is permanently diminished. This condition greatly reduces the efficiency of the lungs, and thereby of the aeration of the blood, and is therefore a cause of disease and a lessened resistance to disease. A factor in causing heart strain in soldiers is excessive 'smartness' of the drill in certain regiments. Men are taught to move so promptly at the word of command that *they anticipate orders* with strained attention. This is harmful, and probably quite unnecessary." The annual urges that training should commence gradually and should never take place *before breakfast or for too long a time.* It is argued that it is not an advantage to train soldiers to be good acrobats or heavy weight lifters, and that training should be carried on with a *constant view to avoid strain on the heart.*

THE CORRECTION OF DEPRESSED AND IRREGULAR DEFORMITIES OF THE NOSE BY MECHANICAL REPLACEMENT

WITH REPORT OF CASES TREATED BY THE AUTHOR'S COMBINED BRIDGE AND INTRANASAL SPLINT *

WILLIAM WESLEY CARTER, A.M., M.D.
Assistant Surgeon Manhattan Eye, Ear and Throat Hospital
NEW YORK CITY

A year ago I called attention to an apparatus designed for the purpose of bringing into proper position the several parts of a depressed nasal arch and holding them until union had occurred. Some months after my first presentation of this subject I learned of an apparatus used several years ago for the support of a depressed fracture of the nose by Dr. O. B. Douglas. Dr. Douglas' device consisted of a mask fitted over the nose and fastened around the head by a band; to this was attached a bar extending above the nose. Holes were bored in the nasal bones, and through these sutures were passed which were tied to this bar. This appliance differed from mine as much in its mechanics as it did in its technic of application, for it did not give the proper support to the base of the nasal triangle, an important feature of my instrument.

The chief object of this paper is to report the work done and the results obtained, and to suggest the further application of the apparatus to deformities other than those of depression.

My apology for using some illustrations that have appeared before is that they represent the fundamental principles on which the action of the instrument rests, and are necessary to make the text clear.

The bridge of the nose is a bony arch formed by the nasal bones and the nasal processes of the superior maxillæ. The extent to which the latter enter into its formation varies greatly in the skulls of different races and in those of the same race. In examining a large number of Caucasian skulls, I was much surprised to find that from one-half to three-fourths of the nasal elevation was due to the nasal processes of the superior maxillæ, and in some skulls the nasal bones formed only the crown of the arch. The extent to which these processes enter into the formation of the arch is a matter of considerable importance, as will be seen when we come to consider the restoration of a depressed bridge.

The nasal bones articulate with each other, the frontal bone, the superior maxillæ and the vertical plate of the ethmoid, while to the lower edges are attached the lateral cartilages. Traumatic deformities of the nose are due to dislocations at these connections and to fracture of the bones.

Any method of treatment for depressed deformity of the nasal bridge that ignores the mechanical principles of the arch does not rest on a scientific basis, and, therefore, can not produce uniform or satisfactory results. Each word in the definition of the arch carries with it practical significance to the surgeon. An arch is a structure built in a curved line in such a manner that it will retain its position when the structure is supported only at its two extremities. In making a practical application of this principle, we must assume that the arch is made up of an indefinite number of segments, on the proper position and mutual pressure of each one of which depends the integrity of the entire structure. If any of these elementary segments are destroyed or displaced, the segments next in line fall together and the arch is established on a new and lower level, or, if the injury has been very extensive, it may be destroyed altogether. Now, if the segments of bone forming the nasal arch are only displaced by the injury, it is possible that, after the thorough mobilization of the bony structures, the original nasal arch may be restored by applying an apparatus that will exert force along lines that would tend to construct a normal arch; the displaced segments are then drawn back into proper position. If there has been destruction of any of the bony segments, either from extensive injury or, as more frequently happens, from disease, we have a different proposition before us; in this case the piers of the arch (the nasal processes of the superior maxillæ) must be brought closer together narrowing the span of the arch and raising its crown; if this can not be done to the normal extent, our only recourse is the injection of paraffin to fill out the deficiency.

In enunciating the basic principles on which this method of treatment rests, no reference has been made to the septum. It is my belief, founded on an experience in over 300 submucous resections of the septum, that in the adult the septum, as a vertical support, takes no part in the preservation of the nasal arch. It must not be forgotten, however, that the upper edge of the septum, wedged in between the lateral cartilages, is one of the segments of the arch and performs the important function of the keystone, and its displacement means the destruction of the arch.

Many of the methods in vogue for the treatment of fractures of the nose and for the correction of depressed deformities have not been based on proper mechanical principles; in fact, the laws of mechanics have been altogether disregarded. It is unnecessary to refer to the various means that have been proposed for meeting the conditions; suffice it to say that nearly all exert pressure in one direction only, and, if counterpressure has been applied at all, there has been no combined action between the two and the results have been neither uniform nor satisfactory either from a cosmetic or functional point of view.

The custom prevalent, especially among general surgeons, of placing straps of adhesive plaster across the nose and splints within the nasal cavities in cases of recent fractures, is to be condemned, for not only is the flattening increased by pressure of the straps, but the nasal chambers are broadened by the splints. Both influences tend to produce a flat nose.

It is mechanically impossible for any form of splint, packing, or intranasal appliance to raise or even to support a depressed bridge, for, according to measurements which I made on a large number of cadavers, the roof of the nose, if prolonged downward and forward, would meet the level of the floor at an angle of 70 degrees, while the vertical diameter of the nasal orifice is only three-eighths of the distance from the center of the nasal bone to the floor of the nose. It can be seen at once, therefore, that any intranasal appliance depending on the floor for support would immediately be propelled toward the choanæ by the inclination of the dorsal plain.

It is only by applying a combination of these two forces, one acting from within the nose at its apex and

---

* Read in the Section on Laryngology and Otology of the American Medical Association, Atlantic City, June, 1909. This article is here abbreviated by the omission of several pictures taken from casts of deformed noses. These pictures appear in the Transactions of the Section, and in the author's reprints.

the other from the outside at the base, that the former symmetry of a flattened nasal arch can be restored.

A careful study of the forces employed by Nature in the development of the flattened nose of the infant suggested the following apparatus, which is intended to duplicate these forces. The apparatus, shown in Figure 1, which has been made familiar to many rhinologists by a former presentation, consists of a fenestrated steel bridge, the wings of which are connected by a hinge, and the distance to which they can be separated is regulated by a thumb-screw. The edges of the wings are padded with rubber, and the small holes near the edges permit of gauze padding being stitched on. The second part of the instrument consists of two small hard-rubber splints perforated by four small holes.

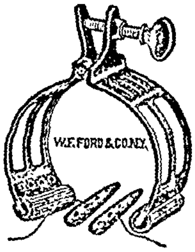

Fig. 1.—Bridge and intranasal splint for correcting depressed deformities of the nose.

The application of the apparatus is as follows, assuming that there is a recent depressed fracture, or, in the case of an old deformity, that the tissues have been thoroughly mobilized by a previous operation to be described later: No. 14 iron-dyed silk is passed through one of the holes in the hard-rubber splint and knotted; the other end is threaded into a large curved needle; this is passed from within the nose through the cartilaginous dorsum just below its attachment to the nasal bones. This process is repeated on the opposite side. The bridge is then applied and the wings adjusted with the thumb-screw to give the proper support to the base of the nasal triangle. The sutures are then run through the fenestræ in the bridge, corresponding vertically to their exit from the nose and drawn tight enough to lift the dorsum into its proper position. The sutures are then tied together over the hinge. There should only be sufficient tension to support the bridge. The diagram (Fig. 2) shows the bridge and splint in position. The splint rests partly under the nasal bone and partly under the cartilaginous dorsum. The resultant of pressure and counter-pressure keeps the apparatus in position; it should be worn for ten days or two weeks.

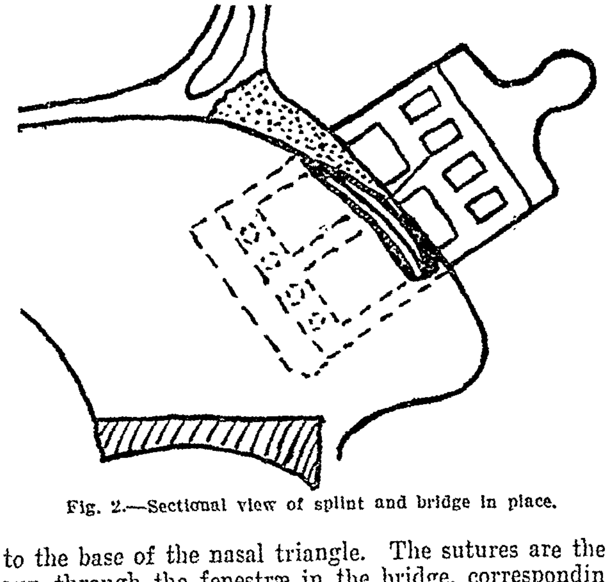

Fig. 2.—Sectional view of splint and bridge in place.

On account of middle-ear complications in two cases, I have ceased using the spray and douche in the after-treatment as previously advised. I now clean out the nasal cavities each day with pledgets of cotton soaked in Dobell's solution and then introduce a small quantity of petrolatum. The wings of the bridge should be carefully padded and the skin where these rest should be bathed each day with alcohol and should be watched for evidences of too great pressure.

The respiratory function of the nose is not interfered with after the first two or three days, and the patients do not complain of great discomfort while wearing the apparatus. It is better for the patient to remain in bed during the treatment, but if the bridge is anchored to the forehead with adhesive plaster he may sit up.

According to Treves, in uncomplicated fractures of the nose, there is fixation in eight days and bony union in two weeks.

The mechanics of the apparatus is shown in the diagram (Fig. 3). A represents the downward pressure applied to the base of the nasal triangle and is produced by the tension of the sutures passing through the dorsum of the nose; B shows the horizontal pressure under the control of the thumb-screw. The resultant force—that actually applied at the base—is represented by a line, C, bisecting the angle formed by A and B, and is the proper direction to support the base of the nasal triangle. A combination of this downward and inward pressure applied at the base and the balancing upward pull at the apex of the nasal triangle when applied to a nose in which the bony framework has been mobilized will tend to construct a normal symmetrical organ. This I have demonstrated on the cadaver as well as on the living subject.

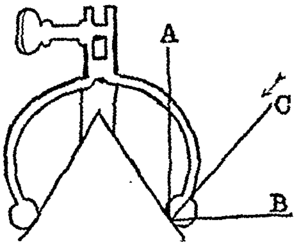

Fig. 3.—Illustrating the mechanics of the intranasal splint and bridge.

External deformities of the nose to which this method of treatment may be considered applicable may be classified as (1) congenital, (2) deformity due to disease, (3) traumatic.

The extent to which those included in the first two subdivisions, that is the congenital cases and those in which deformity is due to disease, can be benefited by this method of treatment depends on the amount of healthy bony framework available for reconstructive purposes. This is always deficient; hence in these cases perfect results are not to be expected without the aid of paraffin.

Traumatic deformities may be divided into (1) recent fractures, (2) deformities resulting from old fractures, (3) habit deformities. The latter consist in deflection of the entire nose to one side, caused by the long-continued effort of the patient to relieve an obstructed nostril by pressing the nose to one side.

In simple recent fractures in which one or possibly both nasal bones are broken and slightly displaced, the fracture can frequently be set by manipulation and a good result obtained without the use of any apparatus. But when the nasal bones tend to separate and in severe cases in which the nasal bones, the nasal processes of the superior maxillæ and the cartilaginous and bony septum are fractured and perhaps comminuted, the basic supports of the nasal arch have been destroyed and an apparatus is needed to hold the parts in proper position during the process of repair. Such cases present ideal conditions for the use of the combined bridge and splints. As soon as the swelling subsides after the injury, the broken parts should be carefully placed in position. The Adams forceps, the handle of a knife, a periosteum elevator may all be found useful in accomplishing this. Particular attention should be paid to the septum, for this is practically always fractured, and the disagreeable features arising from its permanent displacement are familiar to all.

Fig. 4.—Carter's chisel for the nasal processes of the superior maxillæ.

After the apparatus has been applied, the nose should appear normal in shape and it should be retained so until union has occurred.

In old traumatic deformities it is necessary to mobilize thoroughly all the tissues, and, in addition, if the nose is very flat, and there has been loss of tissue, it is frequently necessary to utilize a portion of the nasal processes of the superior maxillæ. A narrow chisel of special design (Fig. 4) is placed against the anterior edge of the nasal process of the superior maxilla and driven upward; the progress of the chisel can be watched by placing the finger on the side of the nose—care should be taken not to go through the skin. When the chisel has been fairly engaged, the strip of bone can be broken off by turning the chisel from side to side. There is little or no danger of splitting the bone into the lachrymal canal, for, as shown by Berens, the grain of the bone runs away from the canal. I found by measurements made on a large number of skulls that the lachrymal canal is about five-eighths of an inch behind the anterior border of the nasal process of the superior maxilla; this places it beyond the danger zone in the normal skull.

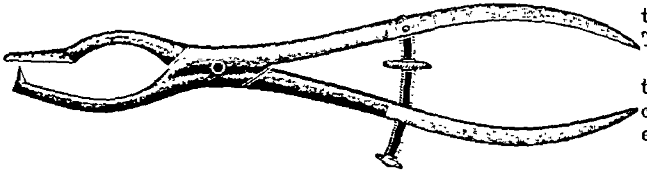

Fig. 5.—Carter's chisel-forceps for cutting through the nasal bones.

Further mobilization of the tissues is accomplished with the Adams forceps (Fig. 6) by placing one blade inside the nose and the other covered with rubber tubing on the outside. The septum is then grasped between the blades and mobilized. A specially devised chisel forceps (Fig. 5) I have found very useful in cutting through the nasal bones near their articulation with the frontal bone. The chisel blade is introduced into the nose up to the desired point, the outside flat blade being covered with rubber tubing and the set-screw carefully regulated so that the chisel will not cut through the skin. In cases in which the septum is badly deformed, a submucous operation should be done a day or two before the bridge splint procedure. When the nose is very flat and the shortened septum is holding down the dorsum, I make an oblique incision through the septum, beginning at a lower level and emerging in the opposite nasal chamber near its roof. This permits the upper segment to be raised without leaving a perforation and is a substitute for the sliding flap operation I suggested last year.

Where there is a step-like deformity caused by luxation of the lateral cartilages at the point of attachment to the ends of the nasal bones, before applying the bridge, I make an incision from within through both lateral cartilages and the septal cartilage along the line of depression with a Myles rectangular septal knife. This enables me to lift the cartilaginous portion of the dorsum into line with the bony portion of the bridge.

The following cases which demonstrate the various circumstances under which the appliance may be found useful are from private practice and from Dr. Harmon Smith's clinic at the Manhattan Eye, Ear and Throat Hospital:

Case 1.—This is reported for the second time to show present condition.

Patient.—An amateur athlete fell from a horse three years ago, striking on his nose. Following the injury the nose was flat and he was unable to breathe through it. The septum was thick, irregular and obstructing. The nasal bones over-rode the nasal processes of the superior maxillæ; the lateral cartilages were displaced backward at the junction with the lower edges of the nasal bones.

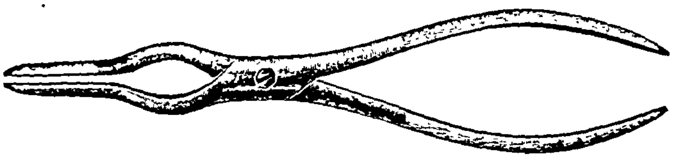

Fig. 6.—Adams' forceps.

Operation.—On Jan. 23, 1908, a submucous resection of the septum was done; two days later the tissues were mobilized and the bridge splint applied. In this case the cartilages of the dorsum had to be lifted in the manner previously indicated. The immediate result was very good.

Present Condition.—There is a slight step-like depression at the juncture of the nasal bones with the lateral cartilages. The contour of the nose is fairly good; the intranasal condition is excellent. Time since operation, 14 months.

Case 2.—This also is reported for the second time to show present condition.

Patient.—Man, aged 24, no venereal history; he has had atrophic rhinitis since early childhood. The nose is broad and flat, almost on a level with the cheeks. Nasal chambers are roomy and covered with crusts. He was treated with daily irrigation of saline solution and massage with 25 per cent. argyrol solution three times a week for six months.

Operation.—In March, 1908, I lengthened the septum by a sliding flap operation and raised the tip and modified the size and shape of the nostrils by an inverted Y-shaped incision (both procedures have been previously described). Before applying the bridge, pieces were chipped from the superior maxillæ to be used in building up the arch.

Present Condition.—Eight months after the operation, elevation of the bridge was only fair; the tip raised and the nostrils were of much better shape. The septum was perforated, the nasal chambers were much smaller and the atrophic rhinitis was greatly improved. Thirteen months after the operation the external appearance of the nose was the same; the atrophic rhinitis was almost gone. The health of the patient was greatly improved.

Remarks.—The bridge in this case is still depressed, but is higher than it was before the operation. This operation was not altogether a success, due to deficiency of tissue with which to build up the arch.

Case 3.—A boy fell on his nose, fracturing it on Sept. 5, 1908.

Examination.—Two days after the injury, the nose was swollen and discolored; a ragged cut extended across the bridge through which the nasal bones could be felt with a probe. The nasal chambers were completely obstructed.

Operation.—Under ether, the fractured nasal bones were found protruding into the nasal chambers. The septum and left nasal process of the superior maxilla were also fractured. The parts were simply adjusted and the bridge splint applied.

Result.—The result in this case was excellent, both as to function and cosmetic effect. The boy tells me that he can breathe through his nose better than before the injury. These good results have continued up to the present time, five months after the operation.

Case 4.—A boy, aged 14, had his nose broken in May, 1908.

Examination.—There was a step-like depression at the point of junction of the nasal bones with the lateral cartilages and considerable over-riding of the nasal bones over the nasal processes of the superior maxillæ, especially on the left side, where there was a large bony protuberance. The nasal chambers were almost obstructed by a thick, irregular septum.

Operation and Result.—In July, I did a submucous resection of the septum, and in October the bridge splint was applied. In this case the septum had to be lengthened. The result was excellent and has remained so up to the present time. The nasal stenosis is completely relieved.

Case 5.—A young man, aged 25, was thrown from his horse on Nov. 28, 1908. He fell on his nose, sustaining the following injuries, case seen four days after the accident: The nasal bones were fractured and separated and over-riding the nasal processes of the superior maxillæ; the septum was fractured. Operation was done Dec. 3, 1908. The result both from a cosmetic and functional point of view was excellent.

Case 6.—A boy, aged 14, was kicked in the nose by a horse on Sept. 16, 1908. He was treated by a local surgeon, who put splints in the nose and fastened strips of adhesive plaster across the bridge.

Examination.—I saw him for the first time four months after the injury. There was a complete saddle-back deformity. On the nasal bridge was a large scar, and a cicatricial band connected the right ala with the cheek. Both nasal cavities were obstructed by an irregular, thick septum.

Operation.—A submucous operation was done and four days later the bridge splint was applied. There was very little bony tissue left to build upon, as the injury was a severe one and some bone had sloughed out. The cicatrix was removed and the bare surface was skin-grafted.

Result.—The result a month after the operation was very imperfect from a cosmetic point of view, though the nasal cavities were perfectly clear and open. I then made a small incision through the original scar, dissected up the scar tissue and skin and injected about thirty drops of paraffin. The present appearance of the patient is greatly improved (due chiefly to the paraffin injected), and he has a good breathing space.

Case 7.—This was a traumatic deformity of ten years standing in a man of 22. There was no depression, but the entire nose was displaced to the left and the right nostril was obstructed.

Operation and Result.—On January 12, a submucous resection of the septum was done and four days later the nasal tissues were mobilized and the bridge splint applied. The result is perfectly satisfactory, the nose is straight and the nasal passages are unobstructed.

Case 8.—A Jewess, aged 18, fell on her nose eleven years ago, fracturing it. She had a pronounced hump on the dorsum, and the entire nose was displaced to the right. The left nostril was obstructed by a deflected septum.

Operation and Result.—A submucous resection of the septum was done on November 20, and the bridge splint operation on November 28. The hump was subsequently removed through a small incision over the dorsum. The result is very satisfactory, the nose is symmetrical and the nasal obstruction is relieved.

CONCLUSIONS

My experience with this method of treatment for deformities of the nose leads to the following conclusions:

1. Cases in which there has been loss of the bony framework of the nose, either from disease or extensive traumatism, are not suitable for this operation.
2. In recent fractures and old traumatic deformities when the tissues have been properly mobilized, this method should yield good results.
3. After a lateral deformity or displacement of the entire nose has been reduced by operation the apparatus should be worn as a retaining splint. For the elasticity of the skin and soft parts tends to restore the former malposition of the organ if it is not so restrained.
4. The passage of sutures from within the nose through the dorsum does not complicate the case.
5. This method of treatment corrects the deformity by reversing the direction of the forces that produced it. It also relieves the intranasal deformity, which we know tends to increase with age and eventually becomes the predominant feature in the case.

69 West Fiftieth Street.

ABSTRACT OF DISCUSSION

Dr. J. O. Roe, Rochester: In recent fractures, I consider Dr. Carter's plan excellent, but in cases of a distorted nose from an old fracture, where a definite amount of osseous tissue has been thrown out and where there is very much thickening of the parts, making the nose much more firm than it was before, the plan which I have adopted in these cases, it seems to me, gives better results than could be obtained by Dr. Carter's fracturing and suspension method. When there is a fracture of the nose, there is displacement of the nasal bones downward and outward, so that there is a flattening of the top of the nose, with a corresponding bulging at the sides. If the top of the nose is lifted according to Dr. Carter's plan, you must, in order to re-establish the normal outline, have as a result a much larger nose, for the reason that the base of the nose is very much wider than before the injury. Even by his plan of completely mobilizing or severing the bones with his chisel, it would be difficult to stretch them out or get them back to their normal position. Another drawback I should think he would encounter is the raising of the top of the nose from the septum, which has also been knocked down and the top line made much lower. It is true, as he has stated, that the arches of the nose form the main support and that the septum has little to do with holding up the bridge, but in liberating the nasal arch from the septum and raising it up and, of course, holding it there until ossification of these bones in their new position has taken place, the septum would stand up as a partition, unattached except at the bottom and ends. Several years ago I attempted to treat some of these cases in this manner by refracturing the bones, somewhat according to Dr. Carter's plan, and supporting them from the inside. One method that I adopted was to use a bridge, somewhat similar to Dr. Carter's and inserting one of the arms of a U-shaped piece of steel and pulling upward on the outer arm at the point opposite to which I wished the pressure on the inside of the nose and which portion I covered with rubber tubing. Another plan that I adopted was to introduce both arms of a jointed triangle into the nose and forcibly separate them by means of a screw, using the floor of the nose for the fulcrum, and having the upper arm bent in the required shape to give the necessary support at the spot desired. As neither of these plans gave satisfactory results, I, of course, never reported them. The plan that I then adopted and which has given me most excellent results is as follows: I make a subcutaneous resection of this displaced bony tissue and by raising the soft tissue from the top of the nose so as to make a place for this resected portion on the top of the bone, thus filling in the depressed portion. In other words, I take the tissue from the place where it is not wanted and place it in the depressed portion, where it is needed, thereby making a symmetrical nose.

The plan that Dr. Carter suggests for raising the tip of the nose, where the lateral cartilages are flattened and bulging outward, by stitching them together so as to draw their bases in, can not fail to be of service in some cases. In the correction of nasal deformities, however, we meet with such an infinite variety of conditions that the plan which works well in one case will not do at all in another, even though the conditions may seem to be quite similar. Every method has its advantages in certain cases, but the conditions of the case must be studied with a view to ascertaining how and in what manner the deformity can be best corrected, rather than to consider the adoption of any one method for all cases. It is therefore only by varying the different methods to meet the requirements of different cases that we can hope for uniformly successful results.

DR. C. F. WELTY, San Francisco: I have operated on one patient in this way and am sorry to say my results were not perfect, although the man was very much improved. He had a very severe extensive traumatic injury, having been thrown against a street car. I have not tried Dr. Roe's plan, but apparently that would work also. Two or three years ago, I transplanted a piece of bone for saddle nose and had better results with that than I did with this apparatus and three years after that transplantation the patient's nose was in perfect condition. I believe, however, that the Carter splint is a splendid method.

DR. R. H. GOOD, Chicago: I have used Dr. Carter's splint with excellent results in a case of marked deformity in which the nose was pushed to one side. I have the pictures both before and after operation. There were several complications which perhaps might have been prevented. For instance, there was sloughing of the cheeks from pressure, which I think could be avoided by having the parts which rest on the superior maxilla flat. Another complication was stitch infection. I used silkworm gut; perhaps if I had used silver it would have been better. I found that the intranasal splint was a little too large for my case, the patient being only 15 years old. The result, however, was very good.

DR. W. W. CARTER, New York: Dr. Roe states that when the bridge of the broad, flat nose is raised the nose will be too large. Now if this were the case I would have to make tissue; for it requires more tissue to elevate a nose and at the same time retain its original breadth, but it does not require more tissue to elevate a nose if we make its base narrower. This is what is accomplished by this method: the excess in breadth of the nose is added to its height by narrowing the base of the nasal triangle by means of the adjustable wings of the bridge. While I do not claim to have obtained perfect results, still I hope that I have succeeded in impressing you favorably with what can be done for a class of patients for which so little has been accomplished in the past. I believe that the instrument is constructed on proper mechanical lines and that by means of it force can be so applied as to construct a normal nose, provided that there is enough bony framework left with which to work.

The sloughing referred to by Dr. Good will not occur if a proper amount of gauze padding is used on the wings, and if the skin under these is bathed each day with alcohol. Then, too, in applying the instrument too much tension must not be employed. I find that silk is the best suture; it is more easily tied and untied, and by capillary attraction it sustains drainage to a great extent. I have had no trouble with stitch abscess. A certain amount of pus always forms around the stitch, but I keep it washed away with boric-acid solution.

No two noses that I have operated on yet have been of the same size or shape, so I seldom use the intranasal splint that comes with the bridge. I usually make them of guttapercha at the time of the operation and mould them to suit each case. Several men have asked me if there is not danger of injuring the turbinate bodies while we are chiseling off the nasal processes of the superior maxillæ: in reply I will say that we are working on a plane anterior to these bodies and do not come anywhere near them.

The Criminally Insane.—Dr. James J. Walsh, New York, favors perpetual confinement of the criminally insane. He holds it absurd that a man may have an attack of mental insaneness that will lead him to take human life, and then be expected to get over his mental condition so as not to be likely to do the same thing again.

VASECTOMY AS A MEANS OF PREVENTING PROCREATION IN DEFECTIVES *

HARRY C. SHARP, M.D.
INDIANAPOLIS

The general public is rapidly coming to realize that our public dependents are largely recruited from the defective classes, and that but comparatively few persons become a public charge as the result of disease or adversity.

Neurologists recognize a so-called predisposition to insanity, which in fact is an inherited defect, or perhaps, more correctly speaking, defects, as there are usually several defective conditions in the mental and nervous organization, and frequently very pronounced physical stigmata.

Sanger Brown says, in speaking of this predisposition, that the phenomena which this condition presents may be readily accounted for by assuming a defect or defects in the neurons (the cell units of which the nervous system is composed) of such a nature that stimuli from environment may not reach the neurons of the cortex, or, having done so, the impression made there may not be sufficiently deep and lasting, or, in other words, well elaborated. Keeping in mind this condition of neuronal defects, it is easy to understand how certain individuals fail to respond to educational influences, moral or intellectual, or both.

That Sanger Brown is correct there is no doubt; and it is equally true that the same condition accounts for the large majority of cases of inebriety, pauperism, crime and drug habit. While defectives fail to respond to moral or intellectual influences, there is another fact that figures very largely, especially in the criminal class. It is that the centers of self-restraint are most defective. These persons may have full knowledge of the nature of their offenses and may fully comprehend that these offenses are morally wrong; still they have not the will-power to resist the impulse to commit a wrongful act when the opportunity presents itself. It is possible that such an individual, who would commit a crime under certain conditions, would be the first to reach the mourners' bench at a Methodist revival. He is as a ship at sea without a rudder, wafted about and changing his course with each variation of wind, all being well if the sea is calm and the weather fair; but a disastrous shipwreck is imminent in the event of a storm.

It does not necessarily follow that a defective person is to become a public charge, for included within this class are to be found the most gifted as well as the most vicious, weakest, and ordinarily, the most unhappy of mankind. Chatterton, Goldsmith, Coleridge and Charles Lamb are but a few instances of the class of gifted defectives. Invention, music and art are sometimes of high order among these persons, but desultory, half-finished work is decidedly more common. Concentrated effort is often impossible to such persons. Executive or business faculty and judgment are seldom developed.

Persons of this character who appear on life's stage and play their part contribute much to the world's beauty and pleasure. They fill a place in history, though history often fails to mention the legacy they leave to succeeding generations in the way of defective children, which become a misery to themselves and a charge on society.

There is no disputing the fact that mental as well as physical defects are transmitted to the offspring. If a defective marries a normal person, frequently the departure from the normal is much less marked in the offspring than it was in the parent, while, on the other hand, if two defective persons marry their children inherit the stigmata of both mother and father, thus becoming a more defective type than either parent.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Naturally the tendency is for the abnormal to mate with their kind—to seeking their own level; then, too, one of this type seldom finds a normal person who would be attracted to him. This condition favors the rapid increase of the number of defectives as well as the accentuation of the type. This class of individuals is very prolific, from the fact that in the matter of sexuality, as in everything else, they know of no self-restraint. They indulge their selfish lust, ad libitum, with no thought whatsoever as to what the result may be; they absolutely refuse to take into consideration their own ability to take care of their offspring. They simply know that they want gratification, and gratification they are going to have.

This is the condition at the present time, and will continue to be so long as this class is permitted to remain fertile.

In addition to the foregoing causes for the rapid increase of defectives, we find that the ranks are being contributed to by persons suffering of some mental, nervous or physical disease or exhaustion, begetting children while suffering from one or more of the above-mentioned conditions. Nature punishes those who violate her laws, and the punishment is visited unto the third and fourth generation. It is very possible that the children of physically exhausted or mentally disturbed parents will manifest a degree of defectiveness.

The children of syphilitics are almost sure to be defectives. Alcoholism, drug habits, immoral excesses are some of the common causes of mental and nervous exhaustion that render a person incapable of begetting normal children. Overwork and many physical maladies which produce in the sufferer a profound mental depression are frequently responsible for defective offspring. Thus it is that we frequently find that the children of ministers, lawyers, doctors and other professional and highly respected business men have pronouncedly disorganized minds, manifesting the same by immoral, criminal or insane acts.

Prenatal impression plays its part in the production of defectives.

Many of you know or have seen physical deformities as a result of profound mental impression during the period of gestation. As the mental faculties are much more highly organized, they are a great deal more susceptible to such impressions. Hence mental markings are more frequent than physical ones. It is very probable that a child of a woman under a mental strain during this period will show some evidence of nervous disorder early in life, and, if not carefully cared for during the critical periods of development, will be the subject of an outburst that will establish it as an abnormal being, beyond the peradventure of doubt.

Several years since a woman who was the mother of a boy at that time serving a sentence in a penal institution told me that during the time she was carrying the boy a man holding a mortgage on her property, taking advantage of her inability to settle the same at the time of maturity, forced a foreclosure, and it excited in her an intense hatred for this creditor. She could think of nothing save his physical repulsiveness and the unprincipled manner in which he had treated her. He was a homely man with very red hair, and she looked on him as a thief and a scoundrel, having robbed her of her equitable right. When this boy was born he had red hair, notwithstanding there was no such thing known in any of his ancestors, and he had always been apparently criminally inclined, although of a respectable lineage. This was undoubtedly the result of a prenatal impression.

The decidedly defective individual is very easily recognized, as the mental abnormality is usually accompanied with prominent physical defects, described by Lombroso, Wiesmann and others as morphologic stigmata. There are quite a number of these stigmata which indicate with considerable certainty the extent and nature of the mental defect. I shall not dwell on the various physical abnormalities that are found in the defective. I do wish, however, to call attention to the two that are found most frequently and the least dwelt on by writers on this subject, namely, imperfect refraction and color-blindness. It is very rare that we find a defective who does not have one or the other of the above-named conditions, though possibly to so slight a degree that the defect may be entirely overlooked. There are persons of this class in whom the only indications are temperamental, the most common being selfishness, ingratitude, inconstancy, egotism, inability to resist an impulse or a desire.

The disposition to permit all classes to procreate without restriction has brought about a condition shown by statistics, the study of which will prove very interesting.

Taking Indiana for the past eighteen years we find the following:

In 1890 the cost of maintaining the inmates in the state institutions, county poor asylum and orphans' homes was $1,201,461.24, while in the year of 1908 the cost was $2,443,140.55, or an increase of $1,241,679.31, which is considerably over 100 per cent. This is for maintenance alone, as none of the appropriations for the purchase of additional property, erecting new buildings or permanent improvements are included in this estimate. Nor is the cost of maintenance of county jails or workhouses included, as I was unable to procure accurate data for this period. But I did learn that in the year 1892 there were 600 jail inmates, as against 1,275 for the year of 1908.

In 1890 there were 8,670 inmates confined in state institutions and asylums for the poor; in 1908 there were 14,398, an increase of 5,728. This relates to such state institutions as those for the insane and feeble-minded, reformatory and penal institutions, poor asylums and Soldiers' and Sailors' Orphans' Home. It does not show the total increase, as the Soldiers' and Sailors' Orphans' Home, which is an institution that in no way should be considered as an institution for the care of defectives, shows a material falling off in its population, while the school for feeble-minded youths, whose entire population consists of the most pronounced defective class, shows an increase from 358 in 1890 to a population of 1,054 in 1908, an actual increase of 696, or over *172 per cent. in the course of eighteen years.* The asylums for the poor do not show anything like such an increase. But these abodes, like the soldiers' and sailors' orphans' homes, hold many persons who are there as the result of adversity and not degeneracy.

Beginning with the Soldiers' and Sailors' Orphans' Home, whose population is made up almost entirely of normal persons and which shows a decrease in population, on up through the county poor asylums, county orphans' homes, prisons, insane hospitals, epileptic village, and institutions for the feeble-minded, each institution shows an increasing percentage in proportion to the extent that it depends on defectives for its population.

In view of the above-described conditions, it seems to me it is race degeneration and not race suicide that should fill us with apprehension. History teaches that the fall of powers and principalities in the past has been due to the weakness of the people and not to the scarcity in numbers. Shall we follow the example of past ages or shall we learn from them a lesson and profit thereby?

Herbert Spencer says that to be a good animal is the first requisite to success in life, and to be a nation of good animals is the first condition to national prosperity. We may become a nation of good animals if we direct the same intelligence to the breeding of human beings that we do to the improvement of the breed of our domestic animals.

Restricting propagation seems to be universally agreed on as necessary for the relief of the downward tendency. The difficulty lies in deciding on the proper method to bring about this restriction. Some have advocated the education of public opinion so that those who are from defective parentage shall, in the face of such public opinion, abstain from marriage. This seems to me even worse than absurd, for I believe that we shall never be able thus to prevent the sexual intercourse; while there might be fewer marriages there would be more bastards.

Restrictive legislation has been advocated and many states have passed restrictive marriage laws. Minnesota has a law providing that within the bounds of the state no marriage shall be permitted either party to which is epileptic, imbecile, feeble-minded or afflicted with insanity, unless the woman be over 45.

Michigan, Delaware, Connecticut, Indiana, New Jersey and North Dakota have also passed laws for the purpose of preventing marriage among defectives, but unfortunately matrimony is not necessary to propagation, and the tendency of these several laws is to restrict procreation only among the more moral and intelligent class, while the most undesirable class goes on reproducing its kind, the only difference being that illegitimacy is added to degeneracy, and thus the children enter on life's battle doubly handicapped.

Dr. R. W. Bruce Smith of Toronto asks:

> What avails the continuous increase of hospitals, asylums, and similar institutions if the number to occupy them grows faster than the accommodations? How can we possibly leave the world better for our work if we do not, at least, begin some action to stop this vicious stream at its fountain-head? . . . Those who have faithfully and patiently wrestled with this perplexing problem have concluded that the only course to be taken is to separate all true degenerates from society and keep them by themselves in carefully classified groups, under circumstances which will insure that they shall do as little harm to themselves and their fellows as possible, and that they shall not entail on the next generation the burden which the present one has borne.

This method of segregation would necessitate the expenditure of enormous sums of money to establish and maintain colonies or industrial refuges which, I believe, would be a disappointment in the end. The colonists would necessarily live under restraint and, unless guarded like actual prisoners, many would escape. In their effort to escape detection these unfortunates would naturally realize that they could not engage in legitimate trade, and therefore would resort to crime, becoming a further menace to society. This plan, moreover, means life imprisonment for a large army of men and women who should be given the opportunity to enjoy life and liberty.

Castration is another means that has been suggested for the purpose of preventing procreation in the unfit. A superintendent of a Kansas institution for the feeble-minded thus operated on forty-eight boys in that institution about the year 1898. He has since severed his connection with the institution and if there has been any further report of his work I know nothing of it. This operation is, as I have repeatedly stated, of too much gravity and causes entirely too much mental and nervous disturbance ever to become popular or justifiable as a medical measure; but I heartily endorse it as an additional punishment in certain offenses.

It can readily be seen that one subjected to castration would in all probability become very morose and downcast on account of the deformity alone. Besides, the testicle has a double function, that of providing an internal as well as an external secretion, and the organism cannot maintain a normal condition when robbed of this internal secretion. This is manifested by the perceptible change in the eunuch.

Since October, 1899, I have been performing an operation known as vasectomy, which consists of ligating and resecting a small portion of the vas deferens. This operation is very simple and easy to perform. I do it without administering an anesthetic either general or local. It requires about three minutes' time to perform the operation and the subject returns to his work immediately, suffering no inconvenience, and is in no way hampered in his pursuit of life, liberty and happiness, but is effectively sterilized. I have been doing this operation for over nine years. I have 456 cases that have afforded splendid opportunity for postoperative observation and I have never seen any unfavorable symptoms. There is no atrophy of the testicle, no cystic degeneration, no disturbed mental or nervous condition following, but, on the contrary, the patient becomes of a more sunny disposition, brighter of intellect, ceases excessive masturbation, and advises his fellows to submit to the operation for their own good. And this is the point in which this method of preventing procreation is so infinitely superior to all others proposed—that it is endorsed by the persons subjected to it. All the other methods proposed place restrictions and, therefore, punishment on the subject; this method absolutely does not. There is no expense to the state, no sorrow or shame to the friends of the individual, as there is bound to be in the carrying out of the segregation idea.

There is a law providing for the sterilization of defectives in effect in Indiana and it is being carried out at the Indiana reformatory. I regret very much that it is not being followed up in the other institutions of the state; but there is no doubt that it will come about in a very short time.

Brown-Séquard, one of the earliest observers of the effect of the secretions of the reproductive glands, said that an extract from the fresh testis, when injected under the skin or into the blood current, had a remarkable influence on the nervous system, mental and physical vigor; that the activity of the spinal centers were greatly improved, not only in cases of general prostration and neurasthenia, but also in the case of the aged. Brown-Séquard maintained that the general dynamogenic effect was due to some unknown substance formed in the testicle and subsequently passed into the blood. Although many of the more recent investigators as Poehl, Zath and others assert that it is found in the external secretion, my own observations lead me to indorse the opinion of the latter.

After observing nearly 500 males in whom I had severed the vas deferens I am prepared to state that there is not only a diminution of the muscular and nervous fatigue resulting from muscular exertion, but also a lessening of fatigue sensation and a decided increase of energy and well being. I have observed splendid results in cases of neurasthenia.

That severing the vas deferens or the oviduct does not arrest the sexual development has been proved by doing the operation on young animals before they reached the period of puberty. That there is no atrophy or cystic degeneration has been satisfactorily demonstrated by ten years' observation. It was on account of these facts that I suggested that the vas deferens in the male and the oviduct in the female be severed as a means of preventing procreation in defectives, as the operation has no deleterious effect on the subject, but the contrary. The operation in no way endangers life.

After cleansing the scrotum with soap and water I bathe the part in alcohol, then grasp the spermatic cord between the thumb and the index-finger of the left hand, detect the vas, hold it firmly and fix it with a pair of bullet forceps, then cut down on it, draw it through the scrotal wound by means of a Tenaculum hook, strip it of all membranes and the accompanying artery, ligate above and sever, cutting away any portion from the vas that may have been damaged in the manipulation. This is done in order that the end next to the testicle may not become closed. It is very important that it shall remain open, in order that the secretion of the testicle may be emptied around the vessels of the pampiniform plexus and there absorbed, for it is through this process that the economy receives the tonic effect of the secretion; also where the end closes there is likely to be cystic degeneration. The action of the muscle closes the skin wound and no stitch, collodion or adhesive plaster is needed. The patient returns to his work immediately and suffers but little inconvenience.

There is no diminution of the sexual power or pleasure. The discharge at orgasm is but slightly decreased.

The operation in the female is more difficult, but, if skilfully done, no more hazardous. The oviduct is reached through a median incision, the tube ligated near the uterus and severed beyond the ligature.

There are over 300 girls in the institution for the feeble-minded in Indiana who, if treated in this manner, would be able to leave the institution and be self-supporting, as the only reason for detention is for the purpose of segregation, as they have not the character to resist the importunities of unprincipled men when thrown on their own resources. The result is that when they are released from the institution they shortly return in a state of pregnancy, or marry some one unable and unfit to rear a family. In either event there is an addition to the dependent class. With the oviduct severed this danger is absolutely obviated. In case of the male the desire for the opposite sex is in no way diminished; his mind is strengthened and his nervous system benefited from the reabsorption of sperm. It has a decided effect on the centers of self-restraint, besides improving the physical condition, as the masturbator refrains from excessive indulgence in this practice. Almost wholly as the result of increased will-power, the rapist or criminal will be aided in resisting his pernicious impulses. Thus we have a means of preventing procreation in the unfit, at the same time improving the condition of the unfortunate individual.

316 Board of Trade Building.

ABSTRACT OF DISCUSSION

DR. L. H. MONTGOMERY, Chicago: If the stigmata of a defective or degenerate are transmitted to the children in many instances, as I firmly believe, how are we going to be entirely satisfied, scientifically and otherwise, that tuberculosis is never transmitted to the offspring? We are all aware that syphilis, insanity, epilepsy and other neurotic conditions are handed down and—due to prenatal influences or otherwise—even alcoholism is inherited or transmitted sometimes. We all see instances of these influences transmitted to the offspring. How are we going to do away, entirely, with this question the author has just raised?

DR. F. C. VALENTINE, New York: Every specialist in genitourinary diseases must agree with the important physiologic and surgical points brought forth by Dr. Sharp. For emphasis it may be permitted to elaborate them by separate discussion. He says that vasectomy is easy to perform; to this one may add that it is the simplest operation in genitourinary surgery. It is well known that the health of the testicle is not impaired by severing its excretory duct, as the testicle does not suffer from occlusion of the duct, as occurs in epididymitis. Moreover, within the last few years many vasectomies have been performed, at White's suggestion, in the hope of thereby relieving prostatic hypertrophy; the testicle, so far as literature shows, was in no wise affected thereby. Two objections to the operation at once occur to the mind, namely: Most, if not all, those operated on were prisoners, therefore the power to procreate was taken from them under duress; it remains questionable that we have a legal right thus to deprive them. On the other hand, the public will soon learn that vasectomy does not influence the power to perform sexual intercourse, but does away with the risk of impregnation. This would lead many sexual profligates to importune physicians for this preventive operation, which involves practically no pain, and, if carefully done, is without danger. To say that no practitioners would be found thus to subvert the purpose of marriage, would be expressing a faith in the morality of the profession even greater than that which I possess. In mitigation thereof, it is but proper to admit that should the person operated on desire the restoration of his procreative function, the continuity of the severed vas and its patency can be restored by a second operation. The restoration of the vas is by far a more delicate and difficult operation; nevertheless, when properly performed, it has proved successful. That vasectomy can impart stamina, moral strength, the ability to resist immoral impulses and temptation, as suggested by the author, is, I must confess, an entirely new idea. While no explanation presents itself for this peculiar psychologic victory, the author merits inexpressible credit for the results he has obtained. His essay will doubtless lead many other surgeons of reformatory and penal institutions to test the question. If the reduction of criminals results his name will go down in history as a notable pathfinder.

DR. W. FORREST DUTTON, Walker's Mills, Pa.: It is not clear to me what is meant by the defective classes and their limitation. We know that with the increase of population the defectives are bound to increase. We cannot yet deny the part played by hereditary influence. I think we have discovered the efficacy of educational factors in many cases, and that instruction should bear a great deal on these things. If we get at the root of all this evil, we will have no trouble at all in preventing the defective classes. In the adoption of so many radical remedies for wrong conditions in the past, I think the educational feature is the factor that should be paramount in dealing with defective classes, whatever they may be.

DR. WOODS HUTCHINSON, New York: Crime is a medical problem in at least half of its extent; and I look forward to the day when the physician will be looked on as the criminologist of the country, and when our police courts and our police administration will be put largely under medical control; and when that time comes we shall save half of the cost of our courts, our prisons, and our poorhouses. We have the humiliating spectacle of the defective criminal insane of the community, 2 per cent., putting to enormous expense and holding in terror the other 98 per cent. of the community, because we have never taken any steps to stop this at its fountain head by preventing this reproduction of defectives. Those questions of the increase of crime are very difficult of settlement; because, in the first place, we are enlarging our definition of crime constantly, making many offenses which were not considered offenses before; as, for instance, in the prohibition communities it is a crime to buy a drink, and in our new tuberculosis campaign we have taken away our former right to spit. Therefore, it is not safe to judge by the apparent increase in the number of convictions. On the other hand, it seems almost certain that these people are at least holding their own with the rest of the community. They have an enormous fecundity. I had the opportunity, recently, of seeing the family records of defective children who had been committed to the New Jersey home at Vineland. Over three hundred records had been taken for the purposes of correctional care. Most individuals had from one to three, and in some cases six or seven, defective relatives; and the families were large, running anywhere from six to twelve and fourteen. The birth-rate is high among such people; on the other hand, they have a very high death-rate, so that helps to keep matters level. About one-third of all our criminals are born of criminal ancestors, and that reproduction might have been prevented if we had taken the matter in hand. Dr. Sharp has made a valuable practical contribution to this question, particularly the fact that it is an operation which is so painless and produces so few undesirable results that defectives are willing to submit to it of their own accord. That, I think, at first appears almost too good to be true; yet those people are not at all desirous of having children; it is not only the feeble-minded who would be glad to be relieved of that responsibility. One of the objections made to this operation is that it might become popular in other classes of the community. By putting these people in this condition we can allow them to return to outdoor life and to a self-supporting existence. Physicians having anything to do with defectives are aware that the most serious practical problem in the care of the female defective is this question of preventing reproduction. These women have to be kept under custodial care during child-bearing life. A feeble-minded man has to find a feeble-minded woman before he can procreate; a feeble-minded woman has no such limitation. A movement of this sort would immensely increase the production of defectives in the community. Whether it is going to be productive of all the moral and hygienic benefits to the defectives themselves that Dr. Sharp claims for it I do not know. It is only fair that the male gland should be subject to the same assaults as the female gland has for twenty years past, and see what the results are. I can easily believe that the criminal and the defective would be rendered more amenable to discipline by this operation, inasmuch as it has been habitually practiced on horses and other animals for the purpose of making them more amenable to control.

Dr. Charles A. Rosenwasser, Newark, N. J.: As vice-president of the Dependency and Crime Commission of New Jersey, I took part in an investigation as to the causes of dependency and criminality, and had occasion to note the important part played by heredity in the development of the defective and delinquent. That there is urgent need of doing something practical and effective to lessen the propagation of the unfit, has been strikingly shown by the investigation conducted some years ago in Illinois, as a result of which it was learned that all the defectives and delinquents in the state at that time, could be traced to one hundred and fifty families. I intend to have introduced into the legislature of New Jersey, this winter, a bill similar to the one introduced in Illinois this year, making the sterilization of habitual criminals compulsory. And, at some later time will take up the defective class. As my work lies largely with inebriates, a class of patients with weakened will power, I am especially interested in the statement that the operation of vasectomy helps to restore the will power, and I hope to be able to test its efficacy in the near future. As to the value of education in lessening the propagation of defectives and delinquents, I am not very hopeful. That education is of very scant value in such matters is seen in the attitude of the medical profession toward the alcohol problem. Physicians as a class are well informed as to the baneful effects of alcohol on the individual and on society, yet among them we find very few total abstainers. If enlightened persons cannot be brought to total abstinence by education, how can we expect to educate a defective or delinquent to abstain from sexual intercourse or from propagation?

Dr. J. N. Hurty, Indianapolis: I have watched the progress of this work with a great deal of interest. I do not think that we have any figures as yet showing that much in a direct way has been accomplished; but I believe that this may be termed a higher hygiene, through which we can hope to better the race. It is futile to educate these people with criminal stigmata. You can't do it. Education does not reach them at all. They have little moral sense, little moral force, and while you can tell them, and they can in turn preach to you the morals of the situation, they will go straight off and commit the acts. They have no will power, no force of mind, to withstand temptation. So education will not reach them. The knife only can reach them. I was at Mr. Vanderbilt's estate at Asheville. He raises all manner of animals there—cats, hogs and dogs—of many varieties. I was standing near the man who was in charge of the beautiful collies at the kennels; one of them (a female) came up to me, and she looked so pleasant that she seemed to me to have a laugh on her face. I patted her on the head, and she was duly grateful for the attention. I asked him, "Do you have any vicious dogs here?" He said: "Do you suppose that we would breed from vicious animals? If a vicious animal appears here we kill it; we have nothing to do with them at all; and the result is that we have no biting animals, but only those amenable to instruction." Why cannot we apply this to the human family? It seems to me that the application is possible; and I would not term it inhuman. It could not interfere with man's rights. A person who is morally defective has no right to impose another defective on the human family. We take from them their lives when they are murderers—hang them, electrocute them—and it is not nearly so severe to take from them their right to procreate. It has already been shown that there are many of this class who prefer not to procreate and voluntarily submit to sterilization.

Dr. W. Forrest Dutton, Walker's Mills, Pa.: I should like to have Dr. Hurty define the limits of this class. That is to say, What is meant by defectives in the broader sense of the word?

Dr. J. N. Hurty, Indianapolis: That would be difficult, indeed. At the present time I would confine vasectomy, if we adopt that method, to those convicted in the courts. We could not extend it further at present; but science may advance some time in the future so that all could be reached. The law in Indiana says that the man shall be examined; if he is found unfit, and has the stigmata of degeneracy, then he is sterilized. The method is not prescribed; any method may be used. That is about as far as we can go at the present time.

Dr. Harry C. Sharp, Indianapolis: In tuberculosis, of course, we are not dealing with a defect. There are families that have low vitality; and it seems to me to be transmitted from one generation to the other. As to the danger of vasectomy becoming popular with a certain class, I fully comprehend that; and I think we should have on the statute books of every state (and we in Indiana realize this since the matter has become so generally understood) a law attaching criminal indictment to any one submitting to this operation or performing the same without due process of law which would be binding. The statement that no one voluntarily gives up the power of procreating, is, in the face of facts, entirely wrong. Many women in this country, and a great many more in Europe, particularly in France, have submitted to major surgical operations in order to avoid procreation. We are all human beings, and we are all submitted to temptation. The one who is normal withstands the temptation; and the one with weaker powers of resistance succumbs. The present law in the state of Indiana, and the only one I think justifiable now, is the one dealing with people in the public institutions. They may have committed crime; they may be in our poor asylum, orphans' homes, insane asylums, or institutions for the feeble-minded. I stated in dictation of my paper (its omission was an oversight of my stenographer) that while the apparent increase in France is not borne out by facts, the definition of crime has been materially extended in several fields; law has been more vigorously enforced. Furthermore, regarding insane asylums, heretofore people have kept their afflicted relatives at home, now they put them in public institutions. All those things contribute to show an increase in criminals and defectives; nevertheless, the actual increase is out of proportion to the increase of population.

I began this work in October, 1899, and from 1899 to 1907 this operation was done on 176 men in the Indiana Reformatory on request. The request was solely for the purpose of relief from the habit of masturbation, and I will give as an illustration the story of my first operation, in October, 1899. A boy 19 years old came to me and asked that he be castrated, as he could not resist the desire to masturbate. I first had him put in a cell with a fellow inmate, thinking that perhaps he would be abashed and the sense of shame would prevent him. He came to me again, still insisting on castration, saying it was just as bad as ever. I did the operation, and two weeks afterward he came to me and said I was just fooling him, that I had not operated on him and he wanted the other operation. I asked him to wait two months and then, if he was no better, I would perform castration. In two months' time he came to me and told me he had ceased to masturbate and that he was all right. I asked him if he had lost any desire or pleasures of the gratification. He said: "No, but I have the will power to restrain myself." That institution conducted a school of letters. This patient was unable to make any progress in the school. Three months after that operation he made satisfactory advance in the school. This was true, practically, of every man operated on; every man who has ceased to masturbate has assigned the same reason: practically every man has told me he sleeps better, feels better and has a better appetite. In that institution the men are sent out on parole. We have satisfactory and unsatisfactory paroles. That is, those men who violate their parole and are brought back to the institution, "jump their parole" (as it is termed), which means that they leave their place of employment and run off. About 65 per cent of the average of that population are satisfactory paroles; that is, of the number of men who are paroled, 65 in 100 receive their final discharge as "satisfactory"; 35 are either returned or leave their place of employment. My last report indicated 203 of the paroles in these men who had been operated on in the last ten years, and 5 of that 203 were unsatisfactory. Since this law was enacted, of course, we have been doing the operation by means of a commissioner appointed. The man's ancestry is inquired into. If the man has had syphilis he is not considered a fit subject to procreate, and he is sterilized. Any man in a criminal institution, when told that he is to be operated on, resents it; so that all these men we have operated on resent it at the time; but subsequently they approve. I have operated on three physicians, and they have all assured me that they have a decided lessening of muscular and nervous fatigue.

The Histology of the Posterior Lobe of the Hypophysis.—Just behind the posterior lobe of the hypophysis, W. Haberfeld (*Anat. Anz.* Sept. 1, 1909, xxxv 98) finds in the human fetus a peculiar structure, the persistence of which might cause some confusion in a post-mortem diagnosis of glioma of the hypophysis. On the Cohnheim theory, this group of cells also affords an explanation of the embryonal rest from which a glioma of the hypophysis would arise. It occurs almost constantly in the fetus (in 5 out of 6 cases) and the new-born (10 out of 11 cases), is about one-fourth the size of the posterior lobe, and is usually found behind and a little below the posterior lobe. The body is made up of very typical glia cells and usually contains a lumen lined with ependymal cells that have very fine cilia. There is no sharp line of division between the glia tissue and the ependymal cells. This body has not been found in the adult or in children older than 3½ months.

THE EFFECT OF INTERCURRENT DISORDERS ON PRE-EXISTING EPILEPSY *

ARTHUR S. HAMILTON, M.D.
MINNEAPOLIS

In the summer of 1899 my attention was first directed to the effect which intercurrent troubles have on epilepsy and mental diseases. At that time, a small epidemic of measles appeared at the State Hospital for the Insane at Independence, Iowa, and, among others, six epileptics acquired the disease. These patients were not under my direct charge, but I saw them frequently, and it was my opinion, as well as that of Dr. Joseph Ohlmacher, in whose immediate service they were, that their convulsions were lessened in number. This opinion, however, was based merely on general observation, and there are no definite records to support it.

The next year, during a prolonged epidemic of typhoid fever, a large number of epileptics became ill, and on the study of these patients my paper is chiefly based. As opportunity offered since that time, I have kept a record of other cases so that now I have notes on a considerable number of epileptics who developed measles, scarlet fever, tonsillitis, pneumonia, grip, gastrointestinal disorders, and pregnancy, or who sustained various injuries, but in nearly all the short duration of the illness, the relative infrequency of the seizures, and the lack of any definite knowledge as to the number of seizures when the patient's general health was good, have prevented me from drawing any positive conclusions, and such cases have been eliminated.

Inasmuch as attacks of petit mal, especially in a large hospital for the insane, are not likely to have been carefully observed in individuals during a state of health, not much has been said here about them. The same is true of psychic equivalents. It is worthy of note, however, that during the typhoid epidemic the patients were carefully observed both day and night by more or less competent nurses, whereas their records previously had been kept by attendants who were by no means always competent or careful. Such error, therefore, as may be due to inaccurate observation is wholly on the side of the contention of this paper. In almost every instance, the bromids were discontinued during the period of acute illness and begun again during convalescence. Abstracts only of histories are given.

Case 1.—*Summary.*—Patient, man, aged 40, single; three cousins were insane. Epilepsy began at 7 years of age; patient sent to the state hospital at 25. Gradual mental deterioration. Severe attack of typhoid in 1896; pleurisy in 1898 and typhoid again in 1900. Previous to latter, three or four major convulsions a month in addition to occasional attacks of petit mal. During forty-six days of typhoid one light convulsion. Toward the end of convalescence, a remarkable diminution in the frequency of respiration. About a year later, another prolonged period of this respiratory disturbance. Subsequent to recovery, convulsions about the same, but mental deterioration more rapid.

History.—Family history was little known except that two cousins on the mother's side and one on the father's were insane. The patient's general health was good so far as known. He had a good common school education; never used liquors to any extent.

Present Disease.—The patient had epilepsy (both petit and grand mal) since 7 years of age. When 24 years old, his mind began to show signs of failure, and the next year he was sent to the state hospital. At that time he usually had from three to twelve fits within a period of thirty-six hours, and then there was an interval of two to four weeks. A stomach aura was usually present. For three weeks before admission he had been sleepless, irritable and despondent; had threatened to cut his throat, and it was feared that he would do violence to others. At times imagined himself in hell, and again thought he was in heaven. He was first admitted to the hospital in 1886, and remained there most of the time subsequently. At first he was pleasant and fairly bright, but as time went on he became more irritable and demented and excessively religious. He had from 1 to 8 severe epileptic convulsions per month, the average being about 3 or 4. In addition to this, there were occasional petit mal seizures.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909. Considerations of space compel the abbreviation of this article in The Journal by giving parts of the case reports in abstract. *The complete article may be found in the* Transactions of the Section and in the author's reprints.

In 1896 he had a severe attack of typhoid fever. There is no record as to the number of epileptic seizures during this illness, but it is noted that during convalescence he had them very frequently. In 1898 he had an attack of pleurisy, lasting three weeks. On July 27, 1900, he was again taken ill with typhoid. His attack was unusually severe and lasted six weeks. During the first twelve days, his temperature was usually 104 to 105, and the highest records, 105.8 and 106, were charted on the ninth day. The nervous symptoms were pronounced throughout. During the greater part of the high febrile period, he was delirious and had a marked tremor, and up to the end of his illness he was greatly confused. He had a very well-marked peripheral neuritis, and for four weeks had albuminuria but no casts. The Widal reaction was first obtained August 2. From August 6 to 10 he was very ill, with low muttering delirium, and his death was daily expected. On August 12 he seemed a little better, and from this time he slowly improved. He had a short epileptic attack with slight convulsive movement August 24. At that time his temperature ranged from 99 to 102, pulse 90 to 110, and respiration almost normal. At the end of August his temperature was practically normal, pulse 85 to 105, and respiration a little above normal. September 1 his temperature went to 101.5. There was then a steady decline in temperature and pulse so that at midnight of September 3 his temperature was 95.8, pulse 90, and respiration 18. Six hours earlier his respiration had been 34. From September 3 to September 8 his temperature slowly rose till on the latter date it was normal. From September 4 to 6 his respiration was from 16 to 18, but on the morning of September 7 it was 5 per minute; at noon, 8, and at 6 p. m., 12; September 8, respiration at corresponding hours, 16, 8 and 10; September 9, 6, 8 and 8; September 10, 6, 7 and 5; September 11, 5, 4 and 4. During this time he slept soundly at night, and even during the day was often found in such deep sleep that it was difficult to arouse him, but aside from this somnolence and his respiration, nothing unusual was observed in his condition. He was considerably emaciated, but was on light diet and was gaining in weight. At 5 a.m. on the 12th he had a severe epileptic seizure, and at 6 a. m. his temperature was 98.8, pulse 88, and respiration 18. At 9 a.m. he had a second severe convulsion, and from this time up to September 17, when he was discharged from the sick ward, his temperature, pulse, and respiration were practically normal. It is worthy of note that though at the time he was taken ill, his respiratory rate was normal, it rose steadily from that time until, on the sixth day of his illness, it was 56, and for ten days thereafter it was in the neighborhood of 40 to 45 nearly all the time, and this without any apparent pulmonary complication. The record of his epileptic seizures for the months preceding and following his illness is as follows: April, 1900, 4; May, 1900, 1; June, 1900, 4, and for twenty-seven days in July, 4. Then there ensued a period of forty-six days during which he had but one very slight attack. In October, 1900, he had two attacks: in November, 3; December, none; January, 1901, 4; February, 1; March, 10.

After he became convalescent, and up till January, 1901, his general condition seemed somewhat improved, but after that time he became worse mentally, was more silly than he had ever previously been, and the attacks of depression which had preceded his illness were succeeded by periods of mild excitement. His weight August 31, 1900, was 101½; by January 1, 1901, it had reached 142½, and on March 31 it was 143½. In April, 1901, he is described as being much more stupid than before, and spending much of his time asleep in his room. His seizures had ranged from one to eight per month in the interval, but were on the average a little more frequent than before the attack of typhoid. In June he was sent to the sick ward on account of his stupidity and "queer feeling" which he had in his head. When received there, his temperature, pulse and respiration were normal, but two days later his respiration again became slow, and during the next four days ranged from 6 to 14 per minute. There was no other change in his condition during this time except that he was very stupid and unusually religious even for him. After coming to the sick ward, he had no bromid, though he had had it previously. On June 12, after praying constantly for fifty minutes, he had a severe seizure at 3 a. m. On June 13 he had two seizures, and on the same day his temperature rose without apparent reason to 102, falling shortly afterward to normal. These seizures had no effect in increasing the rate of respiration. Throughout the remainder of June, all of July, and up to the middle of August, his respiration continued slow, rising gradually during that period from 6 to 12 per minute to about 14 to 20 a minute by the middle of August. He was very greatly disturbed mentally; thought he was to be killed on account of some religious matter, and believed himself cured of epilepsy by the direct intervention of God, though he was at the same time having more numerous seizures than at any previous time of his life. At the end of 1903, he is described as having failed considerably mentally.

Case 2.—*Summary.*—Patient, man, aged 26; single; no occupation. Paternal grandparents defective mentally. Epilepsy began at 17, and mental deterioration was noted a year later. On Sept. 1, 1900, he developed an attack of typhoid fever lasting seven weeks. Albumin and casts were present with very marked irregularity of the pulse. For five months preceding he had an average of fifty-four seizures a month. During the fever he had 3 attacks; in the ensuing three months he had 5, 11 and 10 seizures, respectively.

Case 3.—*Summary.*—Patient, man, aged 27; single; family history negative; at 10 years sustained a severe compound fracture of the skull with considerable loss of bone in the frontal region. Six years later a convulsion followed an attack of scarlet fever. Attacks continued, and at 22 patient was trephined. He was admitted at the state hospital at 26; was irritable and demented. August 2 he went to sick ward with typhoid, which lasted about four weeks. Temperature was 103 to 105.8. Albumin and casts were present. Previous to typhoid, attacks came from four to fifteen per week. There were none during illness and, in month following, seventeen.

Case 4.—*Summary.*—Patient, man, aged 29; single. Epilepsy for ten years. Mental symptoms well marked, but few convulsions. No attacks during a mild run of typhoid. A subsequent attack of acute articular rheumatism with some mental improvement.

Case 5.—*Summary.*—Patient, man, aged 37; married; farmer. Father drank; an uncle was alcoholic and insane. No record of date of onset of epilepsy. Insane four years. A prolonged attack of typhoid in August, 1900, with pleurisy and pulmonary tuberculosis. No seizures during two months of illness and some improvement in general mental condition. Change not permanent.

Case 6.—*Summary.*—Patient, man, aged 22; single; family history unreliable but probably negative. At 16 months of age, following an injury to the head, patient began to have attacks of petit mal, followed later by grand mal; he was admitted at the state hospital in March, 1900. He was in very fair physical condition, but was much demented. He averaged from three to seven convulsions per month when taking bromid, and, in addition, had occasional attacks of mental excitement. In August, 1900, he developed typhoid fever which ran a relatively short course from the date of its recognition, with temperature of 100 to 104. During his illness, the convulsions were about as frequent as formerly, and attending them there were some striking variations in temperature and pulse. Slight improvement mentally and physically during and after convalescence, but no permanent change.

CASE 7.—*Summary.*—Patient, woman, aged 24; single. Maternal cousin epileptic. Epilepsy began at 8½ years. Marked mental deterioration appeared at 15. At 24, patient developed typhoid fever, complicated by pneumonia, otitis media and frontal sinus trouble (?), and running a course of eleven weeks. Seven seizures during her illness, but only one positive attack during the continuance of high fever. Increased mental deterioration and number of seizures after convalescence.

CASE 8.—*Summary.*—Patient, man, aged 31; single. Family and previous personal history negative. Epilepsy appeared at 13. Second admission to state hospital May, 1900. Patient was demented and in rather poor physical condition. August 14 he was found to be ill with typhoid fever, and died twelve days later of intestinal hemorrhage. No seizures during his illness; from ten to twelve per month previously.

CASE 9.—*Summary.*—Patient, man, aged 41; single. Insanity and epilepsy on father's side. At 9 years of age, epilepsy developed. Patient admitted to the state hospital at 34; was irritable and demented. Attacks of grand mal, averaging fifteen to twenty per month. Chronic bronchitis and asthma for some time. In September, 1900, developed typhoid fever, and died on the thirteenth day. No convulsions during his illness.

CASE 10.—*Summary.*—Patient, man, aged 22; single. Epilepsy since 4 years of age. Epileptic attacks frequent, and dementia well marked. In September, 1900, patient developed typhoid fever, and nine days later died of typhoid and croupous pneumonia. No seizures during his illness.

CASE 11.—*Summary.*—Patient, woman, aged 23; single. Epilepsy began at 3 years and continued to her death. In her twenty-third year patient developed typhoid fever and died in the midst of the typhoid in status epilepticus.

History.—Father living and well at 64; drinks moderately. Mother living at 54; has been an invalid for years with some condition causing contraction of the arms and legs. No history of insanitiy, epilepsy, tuberculosis, or cancer in the family.

The patient was as bright as the average for the first three years of her life, and had good health. Menstruation began at 13, and was normal at the time of examination.

Present Disease.—At 3 the patient began to have epileptic fits, from one in three or four months to three or four a day. During the past five or six years previous to admission, the fits were worse at the menstrual period; there was some mental failure for three years, but for four weeks previous to admission, deterioration was very rapid. There had been no convulsions for two months before admission. The patient was incoherent in conversation; appetite poor; slept well; admitted to the state hospital April 22, 1902.

Examination.—Physical condition was negative except for enlarged uterus and increased deep reflexes. Most of the time the patient was quiet and drowsy; occasionally was restless. Her speech was somewhat incoherent; at times drawling and characteristically epileptic; orientation impaired; intellect, memory and mental reaction only fair. She was irritable, confused, and at times emotional; wanted to go home, and said that she was sent to the hospital to die; thought that everyone discriminated against her, and that she was treated badly. She did not want to eat, as she thought that prevented her recovery. During the remainder of April following her admission, she had seizures almost every day; in May, had 24 day seizures, and 4 at night; during June, had 5 seizures in the daytime and 10 at night; was growing constantly more confused. On July 1 she had 3 attacks; on the 2d, 2; on the 3d, 2; on the 4th, 3, and on the night of the 5th, 8. At 8:30 on the 6th she had a convulsion, and this was repeated at 9, 9:30, 10, 10:30, 10:40, and 11:15. Between 11:15 and 12 m. there were five seizures, and from 2 p. m. they occurred every fifteen or twenty minutes, and she died at 4:20 p. m. in status epilepticus.

Autopsy.—This revealed an acute splenetic tumor, recent ulceration of Peyer's patches, enlargement of the abdominal lymphatic glands, and a few hemorrhages into the lungs. A culture from the mesenteric glands showed a pure growth of typhoid bacilli.

CASE 12.—*Summary.*—Patient, woman, aged 19; single. Three brothers had epilepsy. Patient developed epilepsy at 6 years of age, and the disease continued to her death from tuberculous bronchopneumonia at 19. Seizures were about one per day previously to, but much less frequent during her last illness, and entirely absent during last four weeks. At the postmortem examination it was found that, in addition to tuberculosis, she had disseminated cerebral sclerosis.

CASE 13.—*Summary.*—Patient, a boy, aged 11; schoolboy. Alcoholism and insanity in the family. Hemiplegia at 14 months, following an injury to head. Directly after, patient began having convulsions, limited to one side, at first infrequent but later coming as often as three or four per month. At 6, he had a severe attack of typhoid, and after this no more convulsions until at 10 years he had an attack of scarlet fever, after which convulsions reappeared and occurred once or twice a month. Following circumcision and bromid treatment, attacks ceased for eight months.

Family History.—Paternal grandfather drank moderately; father drank to excess at times. Mother died at 37 of consumption; had been insane for two months. One sister was "nervous" preceding her confinement. History otherwise negative.

Personal History.—There was no trouble at patient's birth. He was unusually healthy as a baby. At 14 months, he fell from a chair and hurt his head. There was no external sign of injury. Immediately following this, he had a partial right hemiplegia and shortly afterward began to have fits which were limited to the right side. Each convulsion lasted about ten minutes, and they averaged about one a month. He would become unconscious, fall over, and bite his tongue. Before the accident he could say a few words and could walk, but after it he did not speak or walk for six months. He is now left-handed; before the injury was right-handed. At 6, he had a severe attack of typhoid fever, and was in the hospital for six weeks. Following this he had no more convulsions until he was 10, when he had an attack of scarlet fever, after which they began again, still limited to the right side.

Examination.—When first seen, Sept. 20, 1905, the patient was well developed and well nourished. There was nothing unusual in the formation of head or face. The left hand and arm were distinctly larger and stronger than right; there was practically no difference in the legs. The right pupil was one-quarter larger than the left; the pupillary reflexes were normal. The deep reflexes were slightly greater on the right than on the left; no Babinski, and no Romberg. The foreskin was much elongated and constricted. Physical examination was otherwise negative. The patient was a little slow in responding to questions, and was not quite as bright as other children in school, but the mental defect was not great. Convulsions were occurring from once in two weeks to once a month.

He was referred to the surgical clinic, where a circumcision was done, and he was at once placed on a bromid mixture. He remained under treatment eight months, during which time he had no convulsions, and according to the testimony of his father and his teachers, he was much better mentally.

CASE 14.—*Summary*—Patient, woman, aged 31; married; housewife. Family history negative except that her father showed slight evidence of dementia. Epilepsy began at 17, and eventually she had attacks once or twice a month except during each of seven pregnancies, when they wholly ceased.

Family History.—Father died of an accident at 70; a case of mild senile dementia. Mother died at 68; cause unknown. Five brothers died in childhood; exact cause not stated, but it is said that they had no convulsions. One brother and five sisters are living and well.

Personal History.—The patient's general health was good in childhood; at 2, she had severe diarrhea following teething, but had no convulsions. Since then she was never ill except for the epilepsy. At 13, menstruation began. It was regular, but less in amount than is usual. At 14, she began to do housework and has worked hard ever since. She was married at 20, and has had two miscarriages and five living children. One of the latter died of pneumonia, one of enteritis, and one of "spasms." The two remaining are healthy.

Present Illness.—When about 17, the patient caught cold immediately following the onset of a menstrual period, and the flow ceased; she then had her first convulsion. She cried out, whirled around two or three times, and then fell over backward; bit her tongue, and was unconscious for over half an hour. A second attack occurred a month later. Since then she has had them about once or twice a month except during her pregnancies. The attacks always come on during the night or as she is getting up in the morning. Sometimes there is an aura, "something rushes up into my head;" often there is none. The attack is always preceded by a cry; sometimes by the shaking of the hands. She falls over; has convulsive movements, bites her tongue; froths at the mouth; passes urine, and is completely unconscious. With the beginning of every pregnancy the seizures have ceased and have not returned until after delivery, shortly after which they begin again. They do not appear to have been unusually frequent following the intermission. The physical examination is entirely negative except that the patient has a lacerated cervix and perineum and gonorrheal urethritis.

Case 15.—*Summary.*—Patient, woman, aged 45; married; occupation, housework. Family history negative. Epilepsy began at 26 during her first pregnancy. She has been pregnant four times since, and each time her epileptic attacks have recurred, though she was entirely free from them in the interval. The patient is now demented as well as epileptic. She was seen Aug. 12, 1908, with the permission of Dr. W. M. Chowning.

Family History.—Negative so far as learned. Father and mother died of old age. One brother and a sister are living and well.

Personal History.—The patient was married at 26, and up to that time had been perfectly well. One year after marriage she gave birth to a child. When her pregnancy was three months advanced, she had her first convulsion. She was sitting in a rocking chair, became unconscious; fell over; bit her tongue, and her entire body jerked. After delivery she had no more convulsions until she became pregnant a second time, and another child was born two and one-half years after the first. She had six or eight seizures during this pregnancy. Two years later a third child was born with a similar experience on the part of the mother during that pregnancy. During the fourth pregnancy she had an increased number of convulsions, and also began to show symptoms of intellectual deterioration. At the time of the taking of this history, the youngest child was two years and two months old, and the mother was again three months pregnant. She had no convulsions during the interval, but since the beginning of the pregnancy had had six major epileptic attacks.

She was a well-nourished woman, apparently in good general health, but she had a low and narrow brow and dull, heavy expression. Heart and lungs were normal; arteries moderately thickened; patellar reflexes normal. Pupils were equal and reacted normally to light and distance. The patient was evidently not only an epileptic, but considerably demented. That she should remain free from the attacks in the intervals between her pregnancies seemed almost incredible, but careful questioning failed to elicit any evidence of either petit or grand mal during that time.

Case 16.—*Summary.*—Patient, man, aged 57; hardware merchant, and single. Family and previous personal history negative. Epilepsy began at 32 years of age. At 44 patient had an attack of mental depression with some confusion, lasting about eighteen months without cessation of the convulsions, which occurred from once a week to one every month or two. At 55, he sustained a fracture of the ankle. For two years afterward he showed great confusion, but had no convulsions.

Family History.—Father died at 79, of old age; mother, when comparatively young, of unknown cause. Two half-brothers are living and well. So far as known, there is no other case of insanity, epilepsy or other nervous disorder in the family; no tuberculosis.

Personal History.—The patient was a strong and healthy boy, and aside from his epilepsy had little sickness throughout his life. He used beer and whisky in moderation. He never married. A good many years ago he entered the hardware business, and was able to continue in charge of his store up to 1889, when he was sent to a hospital for the insane.

Present Illness.—In his thirty-second year he awoke one morning to find his tongue sore, his pillow bloody, and his "stomach very much upset." The first positive attack of epilepsy occurred several months later. Shortly after retiring, he fell out of bed in the midst of a convulsion; was unconscious, and bit his tongue severely. A physician was called, and pronounced it "stomachal epilepsy." Attacks occurred at intervals ever since; at first, always at night. For some years he would go for two to eight months without an attack; later, they came much more frequently. He was first admitted to the state hospital Aug. 31, 1889. It was then stated that his mental trouble had been present a little over a week, and it was diagnosed as "acute melancholia." The cause ascribed was "disappointment at the marriage of an adopted niece." When first admitted he was greatly depressed; would not answer questions, and ate very poorly. A couple of months afterward, he is noted as being a little worse, forgetful, and confused. A few days later, a well-marked tendency to suicide appeared. On April 22, 1890, he was taken home "somewhat improved." He was returned on June 2, his mental and physical condition about the same as when discharged. He remained at the hospital a few months, and improved sufficiently to be able to go home again. Later he spent some time in the county hospital, and then was home again for a period of five years. He had never had a guardian appointed when he was at home, and was at least in nominal charge of his business. He was by no means well, however; had convulsions at intervals, ranging from a week to a month or two, and at times talked to himself, and was restless and uneasy. In August, 1902, he became unusually restless, ate little and slept badly. One night he broke the screen from his window and jumped from the second story to the ground, fracturing his left ankle. For two or three days after the injury his mind seemed perfectly clear. He then became greatly confused, and in this condition was sent to the hospital Aug. 26, 1902. There had been no seizures since the accident.

Physical Examination.—The patient was a small man, fairly well developed, and well nourished, with nothing unusual in the conformation of the head. There were many pimples on the skin over the shoulders. The left ankle was fractured. The heart, lungs, and abdominal organs were apparently normal; the radial arteries not thickened. The urine was negative except for the presence of a few leucocytes and red blood cells.

Mental Condition.—The patient's face had a pleasant but rather dazed expression. He entered at once into conversation, but was very much confused; often began, but rarely completed a sentence; seemed to lose the idea before he had fully expressed it, and even when it was recalled to his attention, he was unable to take it up again. He knew that he was at the hospital at Independence. It seemed to him that he had been there before, but he could not say; he was uncertain. When asked how he came to be here this time, he answered: "Well, he said he wanted me—the man that brought me. He said he would take me back there. I suppose they'd let me go again, wouldn't they? The strangers that brought me here?" When asked if he liked it there, he replied: "Well, I guess so far—I guess—well, I don't know. I think I'll be able to walk on that before long, won't I [pointing to leg] ? I suppose likely——" [considerable delay and he was asked what he meant to say] "I suppose it was all right for me to come here, wasn't it? They brought me here—something the matter with my leg or something. I don't know." [Picked at his nose and stared around.] "Well, I suppose that I'd be right here, wouldn't I?" When asked the date, he hesitated considerably; finally gave it as '92; thought the month was August, but could not go further. After a little delay, he named the president and governor correctly.

Course of Disease.—For two years after admission this man was under my care, was closely watched by nurses both day and night, and during that time he did not have an attack of epilepsy or anything resembling one. For a time after admission, he became more and more confused, and finally this reached such a degree that it was scarcely possible to get any meaning from his disconnected words. It was apparent, however, that he was constantly dominated by the idea that he had done something wrong for which he must make reparation. He would try to speak to the doctor about the matter every day during the period of his detention, yet if given time to explain his case, he became so greatly confused that it was impossible for him to formulate even the simplest sentence. His leg healed slowly, but his general health was good. At the end of two years he passed from my observation, but during his last three months he seemed a little less confused and somewhat more cheerful.

Case 17.—Patient, man, aged 28. Sister epileptic. Patient had epilepsy nearly all his life; he was irritable and, in later years, demented. He was admitted Oct. 18, 1897, in status epilepticus. He was unconscious, with frequent seizures; died Oct. 21, 1897, from pneumonia. His temperature was 101 to 102.2. The anatomic diagnosis was: atheroma of aorta; mitral stenosis; croupous pneumonia; cloudy swelling of the liver; scars from former trephine operation; adherent dura mater; thickened pia mater; sclerosis of cornu ammonis.

Case 18.—Patient, man, aged 25, who had had epilepsy since 4 years of age, following measles. No other statement was given as to etiology. Patient was admitted Sept. 23, 1900; died Nov. 2, 1900. Physical examination, at admission, was negative. Patient was much demented; had frequent seizures. October 29 he developed status epilepticus with axillary temperature of 104.2. From this until death, temperature continued high, reaching 108 (axillary just before death). During all this time he was having frequent seizures. Clinical diagnosis was: Status epilepticus with croupous pneumonia. Anatomic diagnosis was: right lobar pneumonia; hypostasis of both lungs; enteroptosis.

That bodily diseases, and also certain physiologic processes, exercise a profound influence on epilepsy has been recognized from the time of the earliest medical records. There is frequent reference in literature to Hippocrates'[1] statement that acute fevers can influence epilepsy both favorably and unfavorably, and, according to Beckhaus,[2] Plato has stated that lepers are free from convulsions. Lanzoni,[3] in 1691, reported the case of a woman who, during three pregnancies, each time had fits twice per month, and was free from them on all other occasions. De la Motte,[4] in 1740, records the case of a woman who became pregnant three times with boys, each time having convulsions, and five times with girls, with no convulsions. This case also developed about 1690. Both cases have been more or less discredited as being possible instances of eclampsia, the albumin test at that time being unknown. Their description, however, certainly does not suggest hysteria, and it does not seem likely that any one could have passed through so many attacks of eclampsia without a fatal result. In 1803 Maisonneuve[5] reported a man who became epileptic after fright on account of a dog-bite. The fits ceased during an attack of intermittent fever, reappearing when the fever was cured. Gérard,[6] in 1846, reported the case of an epileptic girl of sixteen who had about five or six fits per month. She passed through five attacks of intermittent fever, but each time the fits ceased, only to reappear when the fever disappeared.

In 1854, Delasiauve[7] made the first systematic attempt at a collection of cases, and, as a result of his observations, came to the conclusion that practically all severe and acute illnesses suspend or weaken the fits, especially in young epileptics with frequent attacks, this modification being more or less durable, and that chronic ailments diminish rather than abolish the attacks. He also pointed out that, in some cases, the epilepsy persists in spite of intermittent conditions, and may even be made worse by them. Since Delasiauve's time, a voluminous literature has grown up, but much of it consists of reports and observations on isolated cases, on account of which some widely differing opinions have been expressed. Thus, Lannois,[8] as recently as 1893, on the basis of a single case in which, in an epileptic infantile hemiplegic, erysipelas was accompanied by complete suspension of fits, and typhoid fever a little later in the same individual was accompanied by an increase in seizures, was able to come to the definite conclusion that, though intercurrent disorders have frequently a suspensory or curative effect on epilepsy, typhoid must be excluded from the list. In 1857, however, Schlager[9] had reported a case of epilepsy with mental disturbance in which typhoid caused the epilepsy to disappear, and in 1865 Wille[10] stated that the fits ceased during typhoid, but on complete recovery returned with increased severity. Wagner,[11] on the contrary, thought that epileptics were unfavorably influenced by typhoid. In very recent years, several men, such as Friedländer,[1] Séglas,[12] Béraud,[13] Beckhaus,[2] and Pelissier[14] have made more or less extensive collections of cases of intercurrent diseases and of pregnancy in epilepsy, and the opinion of practically all is that during the intercurrent trouble the influence is favorable in most instances, but that afterward the fits are often increased. Indeed, at one time the favorable effect of these conditions on epilepsy as well as insanity was so widely recognized that it was seriously proposed to infect epileptic and insane patients with various diseases; injections of turpentine and sterilized cultures of various bacteria were used a number of times with the hope of producing artificially the effects secured by accidental inoculation, and it was prophesied that some day such means of curing patients, including the building of hospitals for epileptics in malarial regions, would be generally employed.

In addition to the diseases already mentioned, epilepsy is reported to have been favorably influenced by pneumonia, scarlet fever, measles, whooping-cough, loss of blood, and skin eruptions, including the itch, while the favorable influence of traumatic experiences such as wounds and burns, to say nothing of operations, is very widely known. Clarke and Sharp[15] report their experience with epilepsy in twelve cases of measles, German measles and erysipelas, and strongly emphasize their belief that there is little improvement in the epilepsy accompanying these diseases, and that such improvement as is found is not permanent. So far as I know, however, practically no one contends at the present time that the effect of these intercurrent troubles is more than evanescent except in very exceptional cases.

In my series of cases, 11 patients had typhoid or typhoid complicated by some other trouble, and, of this number, 9 showed distinct improvement as respects the number of seizures; 1 was unchanged, and 1 died of status epilepticus in the midst of her attack of typhoid fever. One patient (Case 4) had no convulsions for three and one-half months after his attack of typhoid fever, and was better mentally for one year. In only one instance (Case 13) was there a fairly permanent favorable effect, and in several instances the seizures were really increased in and after convalescence as was also the rapidity of mental deterioration during subsequent months. An epileptic patient of one of the other physicians at the hospital in the same epidemic died of status epilepticus when well along in convalescence, though his epileptic manifestations had been much improved during the period of acute illness. Once tuberculous bronchopneumonia greatly reduced the number of supposedly epileptic attacks. Once typhoid caused cessation of the attacks, which were reinduced, four years later, by scarlet fever. Once pregnancy caused convulsions, and once it caused their cessation. In an old man with a severe traumatism, including fracture, a state of mental confusion was substituted for the attacks, and in two individuals dying of status epilepticus, pneumonia was also found. All the patients were more or less demented in addition to epilepsy, and none showed any permanent mental improvement. In most cases, there was more than the usual amount of mental dulness during the first few days of the typhoid, to be followed by some increase in mental activity in the midst of and toward the end of the disease. Didé[16] says that the convulsions are increased in frequency in the very early period of the typhoid.

As respects typhoid, therefore, my experience is very similar to that of most other writers. The effect, temporarily at least, is almost uniformly favorable, but there are exceptional cases in which the influence is negative (Case 6) or in which it is highly unfavorable and even produces status epilepticus (Case 11). One of Clarke's and Sharp's patients, when well along with measles, died of status epilepticus and pneumonia.

As a rule, the effect of the individual convulsions on temperature, pulse, and respiration was negligible, but in three instances it was quite otherwise. In Case 2 there was, at two periods of the illness, great irregularity of the pulse, lasting several days, both periods corresponding closely in time to the convulsions, though there may have been no necessary connection. In Case 1 there was a remarkable respiratory disturbance at different periods of the illness. At the onset, the respiration was normal, but, as the illness increased, the respiratory rate rose to from 45 to 56 without organic pulmonary disturbance, and remained elevated throughout the period of acute illness. When convalescence appeared to be fairly well established, the respiratory rate had about reached normal. On the forty-second day of the illness, however, it dropped from 16 and 18 on the previous day to 5, 8 and 12. The next morning it was 16, but dropped again during the day to 8, and 10, and on the two subsequent days varied from 5 to 8. On the following day, September 11, it was 5, 4 and 4. The patient was eating fairly well at this time and gaining in weight, and nothing unusual was noticed in his condition except the respiratory disturbance and an excessive somnolence. At 5 a. m. of September 12 he had a severe epileptic seizure, and at 6 a. m. his respiration was 18, and continued normal in rate thereafter up to June 7 of the next year, when it again dropped to 6, and during the next two and one-half months gradually rose to 14 to 20. Seizures occurring during this interval had had no effect on it. In Case 6, also, there was a marked disturbance of pulse and temperature in connection with certain of the individual seizures, but not of respiration, and the disturbance did not accompany all the seizures. Mivart[17] has reported an epileptic patient with the unusually slow pulse rate of 20 to 24.

Friedländer[1] says that there is only one authentic instance (Prieger's[18]) of a cure of epilepsy by typhoid fever. Case 13 of my list would certainly be accepted as a cure if the subsequent history of the patient were not known, for there was a period of four years following the typhoid with no attacks.

Béraud,[13] in his Paris thesis on the "Relations of Pregnancy and Accouchement to Epilepsy," states that pregnancy is not a cause of epilepsy, and that the uterine epilepsy of the ancients is the modern eclampsia. If we disregard the cases of Lanzoni[3] and De la Motte[4] already mentioned, Béraud's statement was probably correct at the time he wrote. In 1890, however, Gudder[19] reported a woman who suffered from epilepsy during both of her pregnancies, and at no other time. Case 15 of my list clearly comes in this group. There are also many cases in literature in which existing epilepsy was made worse by pregnancy, including one additional case of Gudder,[19] Chambrelet's case,[20] Terillon's[21] case, and others. Though there is still considerable dispute as to the usual effect of pregnancy, the opinion of most recent writers is that it is favorable. Thus, in a series of thirty-one collected reports of cases, Béraud[13] found 8 in which its influence was unfavorable, 8 in which it was negative, and 15 in which it was favorable. Of the latter, the suspension of fits was complete in 8 and partial in 7. It may be worthy of note that in one patient (Terillon's[21]), on whom pregnancy had an unfavorable effect, typhoid gave the same result, and in one (Boyé's[22]), in whom pregnancy caused cessation of the seizures, typhoid also caused cessation. In all of Béraud's[13] cases, the effect, if any, was evanescent. Also the effect in the same patient was uniform. Thus, if the first pregnancy caused the fits to cease, the same results always attend subsequent pregnancies. Pearce[23] reported an epileptic patient of Hirst's, with no convulsions from the third month of pregnancy up to nine months after the birth of the child; also three other women who had no fits during pregnancy, but with recurrence after labor; a fifth woman had five children and had no attacks while carrying them, though having an attack once in three weeks at other times. An ovariotomy on this woman had no effect in diminishing the seizures. A sixth woman had an almost identical history. In the same article, S. Weir Mitchell is quoted as saying that he had never seen epilepsy made worse by pregnancy; that, on the contrary, he has often seen it made better, or entirely cease for the period of pregnancy and even into the puerperium. Putnam[24] reports a woman with no seizures during pregnancy, and final cessation of fits.

As already mentioned, traumatism is widely recognized as having a profound effect on epilepsy, usually meaning from his disconnected words. It was apparent, however, that he was constantly dominated by the idea that he had done something wrong for which he must make reparation. He would try to speak to the doctor about the matter every day during the period of his detention, yet if given time to explain his case, he became so greatly confused that it was impossible for him to formulate even the simplest sentence. His leg healed slowly, but his general health was good. At the end of two years he passed from my observation, but during his last three months he seemed a little less confused and somewhat more cheerful.

Case 17.—Patient, man, aged 28. Sister epileptic. Patient had epilepsy nearly all his life; he was irritable and, in later years, demented. He was admitted Oct. 18, 1897, in status epilepticus. He was unconscious, with frequent seizures; died Oct. 21, 1897, from pneumonia. His temperature was 101 to 102.2. The anatomic diagnosis was: atheroma of aorta; mitral stenosis; croupous pneumonia; cloudy swelling of the liver; scars from former trephine operation; adherent dura mater; thickened pia mater; sclerosis of cornu ammonis.

Case 18.—Patient, man, aged 25, who had had epilepsy since 4 years of age, following measles. No other statement was given as to etiology. Patient was admitted Sept. 23, 1900; died Nov. 2, 1900. Physical examination, at admission, was negative. Patient was much demented; had frequent seizures. October 29 he developed status epilepticus with axillary temperature of 104.2. From this until death, temperature continued high, reaching 108 (axillary just before death). During all this time he was having frequent seizures. Clinical diagnosis was: Status epilepticus with croupous pneumonia. Anatomic diagnosis was: right lobar pneumonia; hypostasis of both lungs; enteroptosis.

That bodily diseases, and also certain physiologic processes, exercise a profound influence on epilepsy has been recognized from the time of the earliest medical records. There is frequent reference in literature to Hippocrates'[1] statement that acute fevers can influence epilepsy both favorably and unfavorably, and, according to Beckhaus,[2] Plato has stated that lepers are free from convulsions. Lanzoni,[3] in 1691, reported the case of a woman who, during three pregnancies, each time had fits twice per month, and was free from them on all other occasions. De la Motte,[4] in 1740, records the case of a woman who became pregnant three times with boys, each time having convulsions, and five times with girls, with no convulsions. This case also developed about 1690. Both cases have been more or less discredited as being possible instances of eclampsia, the albumin test at that time being unknown. Their description, however, certainly does not suggest hysteria, and it does not seem likely that any one could have passed through so many attacks of eclampsia without a fatal result. In 1803 Maisonneuve[5] reported a man who became epileptic after fright on account of a dog-bite. The fits ceased during an attack of intermittent fever, reappearing when the fever was cured. Gérard,[6] in 1846, reported the case of an epileptic girl of sixteen who had about five or six fits per month. She passed through five attacks of intermittent fever, but each time the fits ceased, only to reappear when the fever disappeared.

In 1854, Delasiauve[7] made the first systematic attempt at a collection of cases, and, as a result of his observations, came to the conclusion that practically all severe and acute illnesses suspend or weaken the fits, especially in young epileptics with frequent attacks, this modification being more or less durable, and that chronic ailments diminish rather than abolish the attacks. He also pointed out that, in some cases, the epilepsy persists in spite of intermittent conditions, and may even be made worse by them. Since Delasiauve's time, a voluminous literature has grown up, but much of it consists of reports and observations on isolated cases, on account of which some widely differing opinions have been expressed. Thus, Lannois,[8] as recently as 1893, on the basis of a single case in which, in an epileptic infantile hemiplegic, erysipelas was accompanied by complete suspension of fits, and typhoid fever a little later in the same individual was accompanied by an increase in seizures, was able to come to the definite conclusion that, though intercurrent disorders have frequently a suspensory or curative effect on epilepsy, typhoid must be excluded from the list. In 1857, however, Schlager[9] had reported a case of epilepsy with mental disturbance in which typhoid caused the epilepsy to disappear, and in 1865 Wille[10] stated that the fits ceased during typhoid, but on complete recovery returned with increased severity. Wagner,[11] on the contrary, thought that epileptics were unfavorably influenced by typhoid. In very recent years, several men, such as Friedländer,[1] Séglas,[12] Béraud,[13] Beckhaus,[2] and Pelissier[14] have made more or less extensive collections of cases of intercurrent diseases and of pregnancy in epilepsy, and the opinion of practically all is that during the intercurrent trouble the influence is favorable in most instances, but that afterward the fits are often increased. Indeed, at one time the favorable effect of these conditions on epilepsy as well as insanity was so widely recognized that it was seriously proposed to infect epileptic and insane patients with various diseases; injections of turpentine and sterilized cultures of various bacteria were used a number of times with the hope of producing artificially the effects secured by accidental inoculation, and it was prophesied that some day such means of curing patients, including the building of hospitals for epileptics in malarial regions, would be generally employed.

In addition to the diseases already mentioned, epilepsy is reported to have been favorably influenced by pneumonia, scarlet fever, measles, whooping-cough, loss of blood, and skin eruptions, including the itch, while the favorable influence of traumatic experiences such as wounds and burns, to say nothing of operations, is very widely known. Clarke and Sharp[15] report their experience with epilepsy in twelve cases of measles, German measles and erysipelas, and strongly emphasize their belief that there is little improvement in the epilepsy accompanying these diseases, and that such improvement as is found is not permanent. So far as I know, however, practically no one contends at the present time that the effect of these intercurrent troubles is more than evanescent except in very exceptional cases.

In my series of cases, 11 patients had typhoid or typhoid complicated by some other trouble, and, of this

number, 9 showed distinct improvement as respects the number of seizures; 1 was unchanged, and 1 died of status epilepticus in the midst of her attack of typhoid fever. One patient (Case 4) had no convulsions for three and one-half months after his attack of typhoid fever, and was better mentally for one year. In only one instance (Case 13) was there a fairly permanent favorable effect, and in several instances the seizures were really increased in and after convalescence as was also the rapidity of mental deterioration during subsequent months. An epileptic patient of one of the other physicians at the hospital in the same epidemic died of status epilepticus when well along in convalescence, though his epileptic manifestations had been much improved during the period of acute illness. Once tuberculous bronchopneumonia greatly reduced the number of supposedly epileptic attacks. Once typhoid caused cessation of the attacks, which were reinduced, four years later, by scarlet fever. Once pregnancy caused convulsions, and once it caused their cessation. In an old man with a severe traumatism, including fracture, a state of mental confusion was substituted for the attacks, and in two individuals dying of status epilepticus, pneumonia was also found. All the patients were more or less demented in addition to epilepsy, and none showed any permanent mental improvement. In most cases, there was more than the usual amount of mental dulness during the first few days of the typhoid, to be followed by some increase in mental activity in the midst of and toward the end of the disease. Didé[16] says that the convulsions are increased in frequency in the very early period of the typhoid.

As respects typhoid, therefore, my experience is very similar to that of most other writers. The effect, temporarily at least, is almost uniformly favorable, but there are exceptional cases in which the influence is negative (Case 6) or in which it is highly unfavorable and even produces status epilepticus (Case 11). One of Clarke's and Sharp's patients, when well along with measles, died of status epilepticus and pneumonia.

As a rule, the effect of the individual convulsions on temperature, pulse, and respiration was negligible, but in three instances it was quite otherwise. In Case 2 there was, at two periods of the illness, great irregularity of the pulse, lasting several days, both periods corresponding closely in time to the convulsions, though there may have been no necessary connection. In Case 1 there was a remarkable respiratory disturbance at different periods of the illness. At the onset, the respiration was normal, but, as the illness increased, the respiratory rate rose to from 45 to 56 without organic pulmonary disturbance, and remained elevated throughout the period of acute illness. When convalescence appeared to be fairly well established, the respiratory rate had about reached normal. On the forty-second day of the illness, however, it dropped from 16 and 18 on the previous day to 5, 8 and 12. The next morning it was 16, but dropped again during the day to 8, and 10, and on the two subsequent days varied from 5 to 8. On the following day, September 11, it was 5, 4 and 4. The patient was eating fairly well at this time and gaining in weight, and nothing unusual was noticed in his condition except the respiratory disturbance and an excessive somnolence. At 5 a. m. of September 12 he had a severe epileptic seizure, and at 6 a. m. his respiration was 18, and continued normal in rate thereafter up to June 7 of the next year, when it again dropped to 6, and during the next two and one-half months gradually rose to 14 to 20. Seizures occurring during this interval had had no effect on it. In Case 6, also, there was a marked disturbance of pulse and temperature in connection with certain of the individual seizures, but not of respiration, and the disturbance did not accompany all the seizures. Mivart[17] has reported an epileptic patient with the unusually slow pulse rate of 20 to 24.

Friedländer[1] says that there is only one authentic instance (Prieger's[18]) of a cure of epilepsy by typhoid fever. Case 13 of my list would certainly be accepted as a cure if the subsequent history of the patient were not known, for there was a period of four years following the typhoid with no attacks.

Béraud,[13] in his Paris thesis on the "Relations of Pregnancy and Accouchement to Epilepsy," states that pregnancy is not a cause of epilepsy, and that the uterine epilepsy of the ancients is the modern eclampsia. If we disregard the cases of Lanzoni[3] and De la Motte[4] already mentioned, Béraud's statement was probably correct at the time he wrote. In 1890, however, Gudder[19] reported a woman who suffered from epilepsy during both of her pregnancies, and at no other time. Case 15 of my list clearly comes in this group. There are also many cases in literature in which existing epilepsy was made worse by pregnancy, including one additional case of Gudder,[19] Chambrelet's case,[20] Terillon's[21] case, and others. Though there is still considerable dispute as to the usual effect of pregnancy, the opinion of most recent writers is that it is favorable. Thus, in a series of thirty-one collected reports of cases, Béraud[13] found 8 in which its influence was unfavorable, 8 in which it was negative, and 15 in which it was favorable. Of the latter, the suspension of fits was complete in 8 and partial in 7. It may be worthy of note that in one patient (Terillon's[21]), on whom pregnancy had an unfavorable effect, typhoid gave the same result, and in one (Boyé's[22]), in whom pregnancy caused cessation of the seizures, typhoid also caused cessation. In all of Béraud's[13] cases, the effect, if any, was evanescent. Also the effect in the same patient was uniform. Thus, if the first pregnancy caused the fits to cease, the same results always attend subsequent pregnancies. Pearce[23] reported an epileptic patient of Hirst's, with no convulsions from the third month of pregnancy up to nine months after the birth of the child; also three other women who had no fits during pregnancy, but with recurrence after labor; a fifth woman had five children and had no attacks while carrying them, though having an attack once in three weeks at other times. An ovariotomy on this woman had no effect in diminishing the seizures. A sixth woman had an almost identical history. In the same article, S. Weir Mitchell is quoted as saying that he had never seen epilepsy made worse by pregnancy; that, on the contrary, he has often seen it made better, or entirely cease for the period of pregnancy and even into the puerperium. Putnam[24] reports a woman with no seizures during pregnancy, and final cessation of fits.

As already mentioned, traumatism is widely recognized as having a profound effect on epilepsy, usually making it better temporarily. I have not, however, found any case in literature in which the fits have ceased, to be followed by a state of constant confusion over a long period of time, as happened in Case 16. I have the record of an additional case in which, in a girl of 27, an accident almost identical with that in Case 16 happened, resulting in a fracture of both ankles. In this girl, the fits ceased for about two months and were succeeded by a state of confusion less well marked than in Case 16, but the previous history of this patient is so meager as not to render it certain that she had not previously had similar attacks even without traumatism.

Pneumonia, among other acute diseases, is mentioned as causing temporary cessation of fits. In a list of thirty-one epileptics who died of various causes at the Independence State Hospital, and in whom a subsequent autopsy showed croupous pneumonia, I could not find one instance in which it could be absolutely stated that the seizures were less frequent during pneumonia than at other times. On the contrary, there was a clear history of status epilepticus in eleven instances, as occurred in Cases 17 and 18, of which I have only a brief summary of clinical findings to accompany the autopsy records. There were several instances in which no fits occurred during the known period of pneumonia, but this always happened in individuals in whom the seizures were infrequent, and it was impossible to say that they were decreased in number.

How it is that intercurrent diseases can exercise this profound influence on epilepsy is almost as much of a mystery now as when the existence of the relationship was first recognized. It was perhaps but natural that the influence should have been ascribed by many, including Séglas,[12] Toulouse and Marchand,[25] to the fever and the febrile reaction, and favorable results obtained in thyroid feeding have tended to confirm this view. A careful study of cases, however, shows that the degree of improvement in no way corresponds to the height of the fever, and, though the rise in temperature may be a factor, there are certainly other and more important causes at work. The highest temperature recorded in any of my cases was 108, which occurred in Patient 18, who at the time was dying of status epilepticus. The association of high fever, pneumonia, and status epilepticus is certainly a common observation among those who have most to do with the care of epileptics. Friedländer[1] asserts that erysipelas exercises a more powerful and prolonged influence on epilepsy than does typhoid, though the febrile reaction of erysipelas is certainly not so high or so prolonged as of typhoid. Lannois[8] insists that it is not the febrile reaction which induces the change in epilepsy, but the presence of a special poison developed during the course of the intercurrent disease, and this seems the more probable view. It may be that the toxins developed stimulate metabolism—or it may be that in some way the invading toxins awake renewed resistance within the body, possibly in the manner described by Metchnikoff.

Assuming that the intoxication is the proper explanation, numerous attempts have been made by means of artificial inoculation to secure the desired effect, and the results have been uniformly less favorable than in Nature's method. My own most recent attempt was with the Wright method of vaccination. I employed this first with a cataleptic young woman who also had a severe attack of acne. In two days, following the injection of a sterilized staphylococcus culture, there was a very marked mental improvement. The patient got out of bed, walked about, talked fairly intelligently, ate well, and in all respects seemed greatly improved. In two weeks she relapsed completely, and a second and third injection had no mental effect, though the acne disappeared. It is altogether possible, therefore, that the mental change, at the outset, was merely a coincidence. The subsequent use of a typhoid culture in a manic-depressive case, the patient being in a state of depression, was also without effect.

Whether we accept the idea of toxins or of the rise in temperature, however, neither explains satisfactorily the effect of such physiologic processes as pregnancy, nor why typhoid in one person is accompanied by the cessation of seizures, and in another by status epilepticus; nor why pregnancy also can produce absolutely dissimilar effects under apparently similar conditions.

ABSTRACT OF DISCUSSION

Dr. Augustus A. Eshner, Philadelphia: Dr. Weir Mitchell, of Philadelphia, had intended preparing a somewhat elaborate paper on this subject. He had received a number of reports from practitioners in various parts of the country in response to a circular letter, in which experiences were related, showing the inhibitory influence of intercurrent disease on the seizures of epilepsy, and I have gone over the literature for him, most of which has been detailed by Dr. Hamilton. Such an influence, usually temporary, though at times apparently permanent, has been observed since the time of Hippocrates. As Dr. Hamilton has pointed out, therapeutic attempts to control the convulsive seizures by means of the artificial induction of intercurrent disorders, have been made. Scabies has been induced artificially, resulting in a temporary suppression of the seizures of epilepsy. Brown-Séquard in the middle of the last century, noting an analogy between intermittent fever and epilepsy, suggested the development of intermittent fever for the purpose of restraining the seizures of epilepsy. Suggestions of a similar character have been made more recently. Lannois actually employed cultures of staphylococci by inoculation for the purpose of restraining the seizures, and he reports a certain measure of success. After him Marie advised the employment of potassium cantharidinate or some other product of cantharides.

Hessler, an American observer, reported the use of antistreptococcic serum in a series of cases, with good results. Turnowsky has recently reported three cases in which it was believed that permanent recovery from epilepsy was secured as the result of intercurrent pneumonia and scarlet fever respectively, and he seriously advised the exposure of cases of epilepsy to infection with these diseases. Dr. Hamilton has referred to the long list of diseases that appear to exercise an inhibitory influence on epileptic seizures. Typhoid fever has been observed most commonly to exercise such an influence, probably because we see typhoid fever more commonly than any other diseases in epileptics. All infectious diseases, all febrile affections, practically have been noted as exercising an inhibitory effect.

It is well-known that such a result often follows surgical interference undertaken with therapeutic intent. Burns, traumatisms, fractures, the introduction of setons have all exhibited a similar influence. It is difficult to assign an explanation for the influence of intercurrent disease on epilepsy, but Lannois believes that it is due to toxic activity. Dr. Mitchell expressed to me the opinion, and he wished me to voice it at this meeting, that the inhibition is exercised especially in cases in which there is cough. I believe his own observation was made in a case of whooping cough.

Dr. M. L. Perry, Parsons, Kansas: I think it is well to warn those who are inclined to take too hopeful a view of these cases that we should be careful about prognosis. In an experience of six years with epileptics and records of 800 cases we have seen a number of instances where we had temporary relief following various intercurrent diseases, but our records show no case of permanent relief; and it is well to bear in mind that these cases of apparent relief, if they are watched closely, will almost invariably recur, and we have little permanent benefit. I recall but one case of relief of several years' duration, and that was following a severe scald. I do not doubt but that in this case also, the patient being a hemiplegic, there was sooner or later a recurrence. We have had a considerable amount of erysipelas, the usual amount of pneumonia, etc., in our institution, and have noticed their effect in temporarily checking pre-existing epilepsy; but I think we should be very careful in the matter of prognosis, as those cases almost invariably recur.

---

[25] Toulouse et Marchand: Influence des maladies infectieuses sur les accès convulsifs épileptiques, Rev. de psychiat., March, 1899, No. 5.

Dr. A. S. Hamilton, Minneapolis: In the time at my disposal it has been impossible to read all of this rather lengthy paper and that may have led to some misapprehension. Certainly it was not my purpose to give the impression that permanent results could be expected from these intercurrent conditions and that has, I think, been pretty clearly pointed out in this paper. These are interesting observations and that is, up to the present time, all they amount to. Nevertheless, it seems to me that anything which is capable of exercising so profound an influence on convulsions as acute febrile disorders have been shown to produce, is worthy of consideration, and it may be that at a future time, a better knowledge of physiologic chemistry will enable us to take advantage of the therapeutic principle here involved.

BLOOD-SMEARS, THEIR PREPARATION AND STAINING

EMERY R. HAYHURST, A.M., M.D.
Resident Physician, Cook County Hospital.
CHICAGO

The following article has been written to promote the greater use of slide blood-smears in diagnosis by pointing out simple methods of making them. The average physician will not make cover-glass smears; he will go without smears first. They are too tedious and difficult to handle. To illustrate the simplicity of the method of making and staining slide smears, let me say that the physicians in the receiving ward of the Cook County Hospital, working two at a time, and diagnosing from 100 to 200 cases daily, find time to make, stain and examine blood-smears by this method to help in differentiating typhoid, malaria, and miliary tuberculosis from occult (septic) pyogenic conditions, measles from scarlet fever, etc.

I wish, in the first place, to describe an excellent technic for making smears preparatory to staining them, which, though not original with me, I cannot find in the literature. It should be described in every textbook on hematology and clinical diagnosis.

Second, I desire to emphasize the fact that special cleansing preparations of slides and the skin surface for making smears are not necessary. This is exactly opposite to statements in text-books; and the time-saving element must appeal to physicians.

Third, I wish to show how to overcome difficulties in using the Harlow stain. Even the slight differences in technic in the method described from other well-known methods are all-important for success. Although not new in its details, the summary here given has been collected from many sources, carefully sifted out, tested by experiment, and the important features only are here dwelt on. Two points of special importance in the method here given are (1) the economy in the use of the Harlow stain, because one main objection is the expensiveness of the absolute alcohol used, and (2) the self-correction and future dependability of the stain.

METHOD OF MAKING SMEARS

A correctly made smear is of as much importance as the stain. To make broad, uniform smears and not to crush or to distort corpuscles and other elements, as well as to secure an even distribution of all the cellular elements, is the object in view. Use a good quality of glass slides, cleaned by breathing on them and rubbing off with a clean, dry, old linen handkerchief. I rarely find that any other preliminary cleansing or preparation of the slides is needed.

Cleansing of the ear-lobe with alcohol or anything else is likewise seldom necessary; certainly the rubbing creates a hyperemia and gets more blood from an anemic ear, but the lobe of the ear is rarely dirty or greasy enough to contaminate the exuding drop of blood. As an antiseptic precaution, cleansing is also unnecessary, since infection in the ear-lobe is a very remote possibility, and the usual cleansing methods are, at all events, superficial. It wastes the physician's time, and, worst of all, if the ear is left the least bit moist from solutions used, the blood-drop diffuses over the surface of the skin instead of standing up like a bead; the corpuscles are laked or agglutinated; and the resulting smear is worthless. Many physicians are inclined to blame the stain, when the whole trouble lies in the smear. Dropping the needle, or blood instrument, into alcohol after puncturing the ear is commendable, since it may preclude transference of a bacteriemia or contagion from one patient to another.

Probably the best mode of procedure to make slide smears is as follows:

Have two clean slides, A and B, ready. Stick the ear-lobe with a Hagedorn or similar cutting needle. No blood appears, as a rule, until gentle pressure is applied to the lobe. Touch center of slide A to the rounded drop of blood which exudes. Do not press the slide against the skin surface. Now grasp the right end of slide A, with blood drop on top, between thumb and fingers of left hand (palm of hand upward), and hold slide horizontally with its left end directed obliquely away from the body and projecting two-thirds its length over the radial border of the hand. Take slide B in right hand, apply one end to farther edge of drop and pull B back toward you about one-eighth of an inch. This is to make the drop spread by contact sidewise in the acute angle formed between the slides. Next, holding slide B in place, pull slide A steadily backward beneath it and toward your right until the slides slip past one another. The blood-cells adhere to the moving horizontal surface of slide A and fall off from the posterior surface of slide B in a smooth even sheet, uncrushed—in fact, untouched. Dry at once by shaking vigorously in the air. Thus one smear is made on slide A. Slide B may be smeared in exactly the same manner, using the end of slide A for contact. Stain as soon as convenient. Take care that flies do not walk over the surface of the dried smear or the corpuscles will disappear like magic.

It requires much less time to make the smears than the written description of the method would imply, and after a little practice one can make smears with great dexterity and accuracy. Do not use too large a drop of blood. One that does not spread quite to the edges of the slide is best, for then the leucocytes will not collect along the edges of the smear. In making the second smear and all subsequent ones, use a perfectly fresh drop of blood, not the drop that has exuded by itself during the preparation of the previous smear. Smears of other body fluids are made similarly.

DIRECTIONS FOR STAINING IN BRIEF

Use the Harlow[1] (Skelton[2]) stain. The two staining solutions are kept separate, each in a three-ounce, wide-mouthed bottle. 1. Drop the smear, air-dried, but without other fixation, into the eosin stain twenty seconds. 2. Remove, drain an instant against the mouth of the bottle, drop directly into the methylene blue stain twenty seconds. 3. Remove, drain as above, wash rapidly to and fro in a tumbler of tap-water, then shake off the excess of water and blot dry between two folds of filter-paper.

This technic applies to the Harlow stain the principles commonly used in the laboratory for staining sections and smears with ordinary stains, the chief distinctions being the absence of previous fixation or hardening; staining under cover (i. e., the bottles are kept stoppered while staining); there is no washing between stains; and some of the first stain is carried by the smear directly over into the stock solution of the second.

The specimen is ready for examination. The total time spent in staining is less than one minute. Everything is stained—red cells, white cells, the three types of granules, blood-plates, malarial organisms, bacteria, etc., equal to the lithographed plates in text-books. Pleural effusions, ascitic fluids, spinal fluids, pus-smears and similar smears are advantageously stained by this method, since stray red corpuscles which may get into the smear are at once identified by their red stain, whereas lymphocytes, leucocytes, pus cells, mucus, bacteria, etc., show blue.

ADVANTAGES OF METHOD

In a former article[2] I laid stress on the usefulness of blood-smears in general diagnosis and on a special method for using the Harlow stain for cover-glass smears, as well as the many advantages of the stain, and method of staining, as compared with Wright's and others. I prefer the old Ehrlich cover-glass smears for reasons there stated, but the ease with which slide smears are made and stained by the above method deserves special recommendation to busy practitioners.

The method of staining as given above is exceptionally convenient. It will be observed that there is no handling or pouring of the stains at all, no pipettes used, no dilutions on the slide, no special apparatus, preparation, or mixing of stains beforehand, no previous fixation of smears, no soiling of the fingers, table, or aught else, while ordinary tap-water suffices to wash off the excess stain. There is no fear of overstaining should the smear be left in either of the staining solutions; but usually twenty seconds is the minimum time required. With the bottles mentioned, each about half full of stain, the upper end of the glass slide projects well up toward the mouth of the bottle, where it is easily grasped by the thumb and finger. Forceps are unnecessary. The bottles must be kept stoppered at all times, even while staining, and opened only when introducing or transferring the smear. This is to protect the alcohol from evaporation, and to prevent the absorption of atmospheric moisture, and the precipitation of the stains on the surface of the smear. Glass-stoppered bottles are preferable, but corks dipped in melted paraffin will suffice. While staining, the upper end of the slide should be kept clean and dry throughout, so that the fingers need never be soiled.

The 50 c.c. or so of stain in each bottle will keep indefinitely, will stain hundreds of smears, and the liquid is practically never used up, since none is ever thrown away. When the stain gets a little low in the bottles a little more alcohol should be added. When not in use the bottles should be kept carefully stoppered and away from the direct light. An ordinary crayon-box or square cigar-box will answer very well, offering enough room for bottles, filter-paper, slides, etc.

METHOD OF PREPARING STAINING SOLUTIONS

For the sake of completeness the exact method of preparing the staining solutions is here given:

Place one-half gram of eosin (Grübler's water-soluble) in 50 c.c. of absolute methyl (wood) alcohol (Merck's highest purity) in one of the bottles. Similarly place one-half gram of methylene blue (Ehrlich's medicinal) in 50 c.c. of the same alcohol in the second bottle. Do not filter either stain. After dissolving a few hours, the stain is ready for use. Be careful that no water ever gets into either stain. Accurate weights and measurements are not necessary in making up the stains. Both are supersaturated and, in addition, contain insoluble, or slowly soluble, residues.

STAINING TECHNIC AND STAIN CORRECTIONS

On a moment's reflection it is clear that any failure to obtain results in staining a properly made smear must come under one of the four following heads:

1. *Technic of Staining.*—As this consists simply in standing the two stain solutions and a tumbler of water in a row and dropping the smear into each in turn, a mistake here seems improbable. But you must follow directions specifically. Do not try to wash off the excess of methylene blue under the tap—the driving force of the water will take out almost every trace of the blue. There is no occasion to hurry through any of the steps in staining until you come to the washing. This must be done rapidly, but thoroughly enough to rinse off all floating blue stain from the slide. Remember that the blue comes out rapidly and in direct proportion to the time spent in washing. The red stain is removed much more slowly. Three or four quick swashes back and forth should wash it thoroughly. Then with one fling shake the excess water on the floor, touch the lower end of the slide to filter-paper to catch the last drop of water, and finish by blotting dry between two folds of filter-paper, holding the slide and filter-paper carefully in place with left hand while rubbing heavily with the right. The slide should have a pink-red appearance to the naked eye, if the smear is of blood. Use the stains always in the sequence given: red, first; blue, second. Carrying a little of the eosin on the slide into the methylene blue seems to be the main factor in preventing the deterioration of the stain by age.[3] When, by mistake, a little of the methylene blue is carried into the eosin a permanent cloudy precipitate forms in the latter, but apparently not to any real detriment.

2. *Eosin.*—Any sample which will stain red cells when dissolved in alcohol and used alone is all right.

3. *Methylene Blue.*—Any sample which will stain white cell nuclei when dissolved in the alcohol and used alone is all right. It is to be noted that when certain samples of methylene blue are used in the regular stain-

[2] Hayhurst, E. R.: A Satisfactory Method for Staining Blood-smears, The Journal A. M. A., April 3, 1909, lii 1100.

[3] Theoretically the eosin solution becomes more acid by age, owing to slow oxidation in the alcohol. The same applies to the alcohol in the methylene blue solution, but the latter appears to contain enough of slowly soluble alkali to more than correct itself and to be just about balanced by the frequent transference of a slight amount of eosin. Hence the frequency of use of the stain bears some relation to its longevity. When used every few days it appears to keep permanently corrected. When used several times daily the acid eosin finally overcomes the alkaline methylene blue, the nuclei gradually fail to take the blue so well, and correction becomes necessary. A given sample, so used, lasted six months, however, before correction with a drop of alkali became necessary.

ing method a too decidedly alkaline (deep blue) stain results, so that the red cells have a purple or blue tinge instead of the normal pink. Old stains, which have been little used, may take on this tendency. This is doubtless due to a slowly soluble alkaline impurity in the dye or dissolved out of the glass in the bottles. It is easily corrected (see below). With more use the transferred eosin, being acid, will eventually correct it, too.

4. *Methyl Alcohol.*—This is the factor most often at fault. I have always used alcohol recently imported for institutional use and, therefore, fresh. If fresh it is neutral in reaction. Old alcohol may become acid because of the presence of moisture, which, with room temperature and exposure to light, permits slow oxidation of the methyl alcohol to formic aldehyd and finally formic acid. Alcohol obtained through jobbers and supply houses in this country may show this metamorphosis. Peebles and Harlow,[4] however, after calling attention specifically to this defect, have shown how to correct it. In brief, should the stained smear "fail to show any blue," add a drop of strong alkali (20 per cent. potassium hydroxid) to the bottle of methylene blue solution; should it be stained "too blue," with the red cells purple, add a drop of glacial acetic acid to the methylene blue. I find this works admirably. The eosin solution never requires correction—just the methylene blue. Thus the intensity of either stain in a smear, being strictly a question of chemical reaction in the methylene blue solution, is absolutely under control.

As is well known, different bloods vary in the degree of alkalinity they possess. With a given stain properly corrected the normal blood shows only a pale blue nuclear stain, whereas a stain from a case of pneumonia takes an intense dark blue nuclear stain. The red cells are stained red, the depth of red and its distribution depending on the amount and distribution of the hemoglobin. Should the latter show a purple tinge, the blue stain is too alkaline and should be corrected. The granules in the leucocytes are invariably stained (neutrophilic, eosinophilic, basophilic) regardless of slight differences in the chemical reaction of the stain. In order to have perfect stains of all blood conditions it may be well to have two methylene blue solutions, the one made purposely more alkaline than the other. T[illegible]a smear in each. My observation is that any [illegible] which will stain a normal blood so as to show [illegible] erythrocytes, and pale blue nuclei in [illegible] nuclears, suffices for a[illegible] in most of the pathologic conditions [illegible] tion is greater, and the contrasts more marked.

SUMMARY

1. Satisfactory blood-smears may be made by following specific directions.
2. The Harlow stain for blood-smears is utilized in a one-minute method so that it "stains everything" with perfect satisfaction.
3. The method is simple, convenient, and dependable.
4. The physician prepares his own stains to start with.
5. The stain solutions are always ready and keep indefinitely.
6. The stain and method of staining are recommended for dried smears of all kinds.
7. Peebles and Harlow's observations on corrections of faulty eosin-methylene blue stains render control practically absolute.

Clinical Notes

INTRAMEDULLARY TUBERCULOMA REMOVED AT THE LEVEL OF THE FIFTH THORACIC SEGMENT OF THE SPINAL CORD

NOTE ON BEHAVIOR OF THE CEREBROSPINAL FLUID *

WILLIAM C. KRAUSS,† M.D.
Neurologist to the Buffalo General Hospital

WITH SURGICAL REPORT

By EDWARD R. McGUIRE, M.D.
Associate Surgeon, Buffalo General Hospital
BUFFALO, N. Y.

Patient.—A. G., aged 36, American, a wood-working machine hand, entered Buffalo General Hospital, Dec. 26, 1907, complaining of general weakness and pain in the left side of chest.

History.—His father died of old age at 82; mother is living and well at 65. He has five brothers and three sisters living and well. One brother died of typhoid fever at 44. There was no family history of tuberculosis, cancer or rheumatism. Patient had three children living and well; wife had had no miscarriages. Patient had had measles, mumps and whooping cough in childhood and had typhoid fever in 1892; was sick in bed about four weeks. Had influenza in spring of 1907 and a slight attack of pleurisy in summer of 1907. Since that time had been unable to do anything, because of general weakness and pain in various parts of body. Had been hard of hearing in right ear since having had influenza, health being good up to that time. Six or seven years ago patient had an operation for what was probably an hydrocele of left testicle. Last spring the right one began to be similarly affected. About one month before he was seen the left one again seemed to be enlarging. He denied all venereal history. His normal weight was from 135 to 140 pounds. One month before he was seen he weighed 117 pounds. Most of his weight had been lost since early in the summer of 1907. Smoked and chewed tobacco and drank moderately.

Present Illness.—Since about Dec. 1, 1907, patient had been growing markedly weaker. He had pain in left chest, especially when lying down and on deep inspiration. During past summer patient had frequent night sweats, and since Dec. 1, 1907, he had had profuse night sweats every night. Had no special cough. Bowels were constipated; during the two weeks before he was seen nothing but an enema proved successful.

Examination.—This showed a fairly well developed but poorly nourished man. Pupils reacted normally. Tongue coated with grayish fur. Chest showed poor expansion throughout; less on right in supra- and infraclavicular regions. The heart [illegible] normal in size and position. Patellar reflexes were exag[illegible] ankle clonus and Babinski sign present.

M. 55-co
M. 14 in-
tracerebr

[illegible]cember 27, 1907: On right side in suprascapular re[illegible] breathing was bronchial in quality; in the infrascapular, it was exaggerated. Epididymis on each side was very hard and large. Glands in groin were somewhat enlarged, also along Scarpa's triangle. Suggestion of ankle clonus; knee-jerk quick. Some crepitus in left knee-joint on flexion; less in right knee.

December 29, 1907: Blood examination showed: hemoglobin, 85 per cent.; red corpuscles, 5,080,000; white corpuscles, 7,200; differential polymorphonuclears, 75 per cent.; large lymphocytes, 5.5 per cent.; small lymphocytes, 14.5 per cent.; eosinophiles, 3 per cent.; basophiles, 2 per cent.

January 3, 1908: Fluoroscopic examination showed two distinct areas of shadow in the left chest. Right chest was clear. Left chest was slightly darker over upper lobe than on the right side same point. Patient returned to his home unimproved after a period of two weeks. The bowel movements became involuntary. A few days later he lost control of the bladder, and the urine passed involuntarily. The legs became suddenly weaker, and the pain in the lower part of the body and right leg increased in severity. He was seen by Dr. E. R.

* Read at the meeting of the Eighth District Branch of the Medical Society of the State of New York, held at Batavia, N. Y.

† Dr. Krauss died September 21, after this paper was accepted for publication.

DIRECTIONS FOR STAINING IN BRIEF

Use the Harlow[1] (Skelton[2]) stain. The two staining solutions are kept separate, each in a three-ounce, wide-mouthed bottle. 1. Drop the smear, air-dried, but without other fixation, into the eosin stain twenty seconds. 2. Remove, drain an instant against the mouth of the bottle, drop directly into the methylene blue stain twenty seconds. 3. Remove, drain as above, wash rapidly to and fro in a tumbler of tap-water, then shake off the excess of water and blot dry between two folds of filter-paper.

This technic applies to the Harlow stain the principles commonly used in the laboratory for staining sections and smears with ordinary stains, the chief distinctions being the absence of previous fixation or hardening; staining under cover (i. e., the bottles are kept stoppered while staining); there is no washing between stains; and some of the first stain is carried by the smear directly over into the stock solution of the second.

The specimen is ready for examination. The total time spent in staining is less than one minute. Everything is stained—red cells, white cells, the three types of granules, blood-plates, malarial organisms, bacteria, etc., equal to the lithographed plates in text-books. Pleural effusions, ascitic fluids, spinal fluids, pus-smears and similar smears are advantageously stained by this method, since stray red corpuscles which may get into the smear are at once identified by their red stain, whereas lymphocytes, leucocytes, pus cells, mucus, bacteria, etc., show blue.

ADVANTAGES OF METHOD

In a former article[2] I laid stress on the usefulness of blood-smears in general diagnosis and on a special method for using the Harlow stain for cover-glass smears, as well as the many advantages of the stain, and method of staining, as compared with Wright's and others. I prefer the old Ehrlich cover-glass smears for reasons there stated, but the ease with which slide smears are made and stained by the above method deserves special recommendation to busy practitioners.

The method of staining as given above is exceptionally convenient. It will be observed that there is no handling or pouring of the stains at all, no pipettes used, no dilutions on the slide, no special apparatus, preparation, or mixing of stains beforehand, no previous fixation of smears, no soiling of the fingers, table, or aught else, while ordinary tap-water suffices to wash off the excess stain. There is no fear of overstaining should the smear be left in either of the staining solutions; but usually twenty seconds is the minimum time required. With the bottles mentioned, each about half full of stain, the upper end of the glass slide projects well up toward the mouth of the bottle, where it is easily grasped by the thumb and finger. Forceps are unnecessary. The bottles must be kept stoppered at all times, even while staining, and opened only when introducing or transferring the smear. This is to protect the alcohol from evaporation, and to prevent the absorption of atmospheric moisture, and the precipitation of the stains on the surface of the smear. Glass-stoppered bottles are preferable, but corks dipped in melted paraffin will suffice. While staining, the upper end of the slide should be kept clean and dry throughout, so that the fingers need never be soiled.

The 50 c.c. or so of stain in each bottle will keep indefinitely, will stain hundreds of smears, and the liquid is practically never used up, since none is ever thrown away. When the stain gets a little low in the bottles a little more alcohol should be added. When not in use the bottles should be kept carefully stoppered and away from the direct light. An ordinary crayon-box or square cigar-box will answer very well, offering enough room for bottles, filter-paper, slides, etc.

METHOD OF PREPARING STAINING SOLUTIONS

For the sake of completeness the exact method of preparing the staining solutions is here given:

Place one-half gram of eosin (Grübler's water-soluble) in 50 c.c. of absolute methyl (wood) alcohol (Merck's highest purity) in one of the bottles. Similarly place one-half gram of methylene blue (Ehrlich's medicinal) in 50 c.c. of the same alcohol in the second bottle. Do not filter either stain. After dissolving a few hours, the stain is ready for use. Be careful that no water ever gets into either stain. Accurate weights and measurements are not necessary in making up the stains. Both are supersaturated and, in addition, contain insoluble, or slowly soluble, residues.

STAINING TECHNIC AND STAIN CORRECTIONS

On a moment's reflection it is clear that any failure to obtain results in staining a properly made smear must come under one of the four following heads:

1. *Technic of Staining.*—As this consists simply in standing the two stain solutions and a tumbler of water in a row and dropping the smear into each in turn, a mistake here seems improbable. But you must follow directions specifically. Do not try to wash off the excess of methylene blue under the tap—the driving force of the water will take out almost every trace of the blue. There is no occasion to hurry through any of the steps in staining until you come to the washing. This must be done rapidly, but thoroughly enough to rinse off all floating blue stain from the slide. A given sample, so used, lasted six months, however, before correction with a drop of alkali became necessary.

THE TRANSMISSION OF EPIDEMIC POLIOMYELITIS TO MONKEYS

A FURTHER NOTE *

SIMON FLEXNER, M.D., AND PAUL A. LEWIS, M.D.
NEW YORK

In a previous communication[1] we presented in the form of a chart the results secured up to that time in producing poliomyelitis in monkeys by injecting intracerebrally a virus, denominated M.A., obtained from the spinal cord of a child suffering from epidemic infantile paralysis. The virus had been passed successively through three generations of monkeys and is still being transmitted.

We desire in this communication to present the results in the form of a chart[2] obtained up to this time with the second virus, denominated K. It is, in our opinion, desirable that the facts thus far secured relating to this virus be published, since they extend considerably the previous observations.

In the first place, it can now be affirmed that the virus of poliomyelitis cannot be very difficult of transmission to monkeys under the conditions leading to the development of the lesions and symptoms characteristic of epidemic poliomyelitis in man, since both specimens of human cord furnishing the original virus have sufficed for the transmission of the disease successively.

In the next place, it can now be stated that it is not absolutely essential that the virus be introduced into the brain, but that successive transmission is possible by way of the peritoneal cavity (Monkeys 27 and 40), by intravascular injection (Monkey 52), and by intraneural injection (Monkey 16). The lesions in the monkey in which the virus was introduced into the sheath of the sciatic nerve developed first on the side inoculated and later extended to the opposite side of the spinal cord.

On the other hand, it cannot yet be affirmed that still other avenues do not exist for the entrance of the virus into the central nervous system. Additional observations are required and are, indeed, in process of being made, before the statement can be ventured that infection does not occur by way of the skin, the respiratory passages and the digestive tract.

The conclusions to be drawn from the experiments related are to the effect that the virus of epidemic poliomyelitis is readily transmissible from man to monkeys and from monkey to monkey, by way of the brain, the peritoneal cavity and the circulation, and that, however transmitted successfully, it becomes established in the spinal cord and medulla, where it sets up characteristic lesions which are followed by equally characteristic effects that exhibit themselves as the usual symptoms of infantile paralysis in human beings.

Moreover, it can now be stated that this experimental form of poliomyelitis in monkeys is a severe and very often a fatal disease, and when recovery from the disease takes place there persist residues of paralysis which resemble the paralytic effects also persisting in human subjects of poliomyelitis.

[1] THE JOURNAL A. M. A., Nov. 13, 1909, liii, 1639.

[2] In the chart M. signifies monkey.

McGuire early in March, who suspected spinal cord tumor, and induced him to re-enter the Hospital March 4, 1908.

March 5, 1908: At Dr. McGuire's request I examined the patient and found him pale, weak, emaciated, lying on his right side, complaining of a great deal of pain over the chest, especially the left side, which had defied all manner of treatment for many months. Movement of the body did not seem to aggravate the severity of the pain, and patient was as comfortable on his left side or back as on his right side. Inspection showed the legs drawn up, flexed at the thighs and knee joints, and atrophied to a very marked degree; there was no difference in measurements between the right and left leg—both were practically reduced to skin and bones. The muscles of the arms, however, were quite well preserved, and not wasted to the extreme which characterized the lower extremities. Some slight degree of stiffness bordering on contracture was present in the legs. The abdomen was flattened; urine and feces were passing involuntarily. No bed sores were present. Testing the muscular strength of the legs gave an absolute negative result. No motion of any kind could be detected from the chest caudad whatever. The patellar tendon reflexes were slightly exaggerated; ankle clonus was slightly exaggerated; patellar clonus was absent; Babinski's reflex and plantar reflexes were slightly present on both sides; the cremasteric and abdominal reflexes were absent. Testing the skin for sensation revealed an anesthesia complete for all forms caudad of the intermammillary line. The ventral level was quite sharply defined, but the dorsal level was marked by a zone of 1½ inches in width, in which the differentiation was less marked. In this zone of uncertainty the patient would be unable to distinguish between sharp and dull objects; would give contradictory answers, and on successive examinations would interchange the anesthetic, hypesthetic and normal areas. Examination of the spinal column elicited by deep pressure a sensitive area over the third to fourth thoracic spinous processes. No deflection or deformity of the spinal column could be detected. On his first stay in the hospital, the temperature on three occasions rose above normal; the pulse ranged from 80 to 90, while the respirations continued 20. Urinary examinations showed absence of albumin and sugar, normal specific gravity, and an occasional leucocyte and granular cast. On the second stay at the hospital, the temperature rose above 100 F. on two occasions, and the pulse ranged from 90 to 100.

Reviewing the clinical history of this case, we have a man without any tuberculous or specific history, attacked by influenza in the spring of 1907, and followed by a weakening of the whole body, pain[illegible] and a slight attack of pleurisy in the s[illegible]cial apparatus, the testicles became involved, he began to[illegible]hand, no pre- and in December, 1907, the process see[illegible]ers, table, with increasing vigor. With continuou[illegible] to wash of the legs advanced to such a degree th[illegible] staining to enter a hospital. A very careful ex[illegible]ing solu- chest by an experienced clinician revea[illegible]berculous process in the left lung, which was verifi[illegible] the radiograph. All attention was paid to the thoracic contents, and as the pain and weakness and loss of weight could be attributed to the chest lesion, no attention was paid to such symptoms as "marked constipation, patellar reflexes exaggerated, ankle clonus and Babinski present."

Returning home, the symptoms of cord disease advanced much more rapidly than the chest symptoms; bladder disturbances, rapid loss in strength, increasing weakness of the legs even to complete paralysis, exaggerated deep reflexes and absence of the superficial reflexes, all pointed to a slowly increasing intraspinal pressure; the zone or level of anesthesia at the height of the intermammillary line, and the area of sensitiveness over the third and fourth spinous processes spoke for a lesion at the level of fifth thoracic segment. Although the patient was not in a very favorable condition for an operation, his relatives were very favorably inclined, and the patient most desirous for any kind of relief. A laminectomy was agreed on at the earliest moment.

SURGICAL REPORT BY DR. E. R. M'GUIRE

The patient was told of his desperate condition, and little if any hope was given him of recovery. He requested to have something done, however, even with so slight a prospect of success. March 10, 1908, an incision was made from the first to the seventh dorsal vertebra. The muscular attachments were easily separated with comparatively slight oozing. The second, third, fourth and fifth spinous processes were removed with a rongeur forceps, and the canal opened at the fifth spinous process with hammer and chisel. Then with a Doyen forceps the canal was opened from the fifth to the second thoracic spinous process. The dura appeared normal and even palpitation of the cord revealed no evidence of tumor. On opening the dura, the pia appeared dull and of a different consistency at the second dorsal spine. Closer inspection showed a distinct tumor formation involving the greater part of the interior of the cord. With the blunt end of a dressing forceps, the tumor was shelled out with perfect ease. There was very little hemorrhage at any time. After removal of the tumor there was a small section of the cord still intact. The pia and dura were sutured with plain catgut, and the external wound closed with thread, without drainage. The patient left the table in very poor condition. Continuous salt solution per rectum was immediately started, also a subcutaneous injection of 300 c.c. of salt solution containing 0.6 per cent. of adrenalin chlorid. The patient failed to rally, and died one hour later. Permission to reopen the wound was obtained, and the cord was removed and sent to Dr. Burton T. Simpson for examination.

Pathologic Report by Dr. Simpson: The tumor, as received at the laboratory, was 2 cm. by 1.5 cm. (¾ in. by ⅝ in.) in size, of very firm consistency. Cut section showed a glistening white homogeneous surface. Microscopically, the periphery showed numerous giant cells, while the central part was composed of a dense fibrous tissue. Section stained with carbolfuchsin showed a few tubercle bacilli. A section of the cord, at the area where the tumor laid, showed the cord structure completely destroyed, while a section taken about 5 cm. (2 in.) below showed complete degeneration of both ascending and descending tracts. Microscopic diagnosis of the tumor is given as tuberculoma.

This case is unusual in that an intramedullary tuberculoma could exist without producing dissociation of sensation. Repeated examinations were made to test sensation, but patient's answers were always the same.

A phenomenon which I observed during the course of the operation may be of some service in locating the sit-filter-p[illegible] of the tumor after the dura has been exposed, in place[illegible] the tumor is intradural, or intramedullary. right. The slide[illegible]ulk of the cord produced by an intra- the naked eye, if the smear is of [illegible] will completely occlude always in the sequence given: [illegible]upt the passage or flow or the [illegible] fluid. There will result a damming back of the cerebrospinal fluid cephalad of the constriction and an increased tension will follow. Caudad of the constriction (tumor) the cerebrospinal fluid will be diminished in tension, owing to the cutting off of the normal tension and circulation. Incising the dura cephalad of the tumor will cause a spurting of the cerebrospinal fluid, a jet being projected from several inches to a foot or more in height, according to the tension or force of the fluid; while caudad of the tumor, an incision into the dura will cause only a welling out of the fluid from the aperture, flooding the field of the operation without any force or tension. Observing the behavior of the fluid, the surgeon will know whether he is cephalad or caudad of the tumor, and can make his incision accordingly.

This phenomenon has been observed several times at the Buffalo General Hospital, and it is believed that it has some significance and value in detecting the situation of intradural tumors after exposure of the dura.

THE TRANSMISSION OF EPIDEMIC POLIOMYELITIS TO MONKEYS

A FURTHER NOTE *

SIMON FLEXNER, M.D., and PAUL A. LEWIS, M.D.
NEW YORK

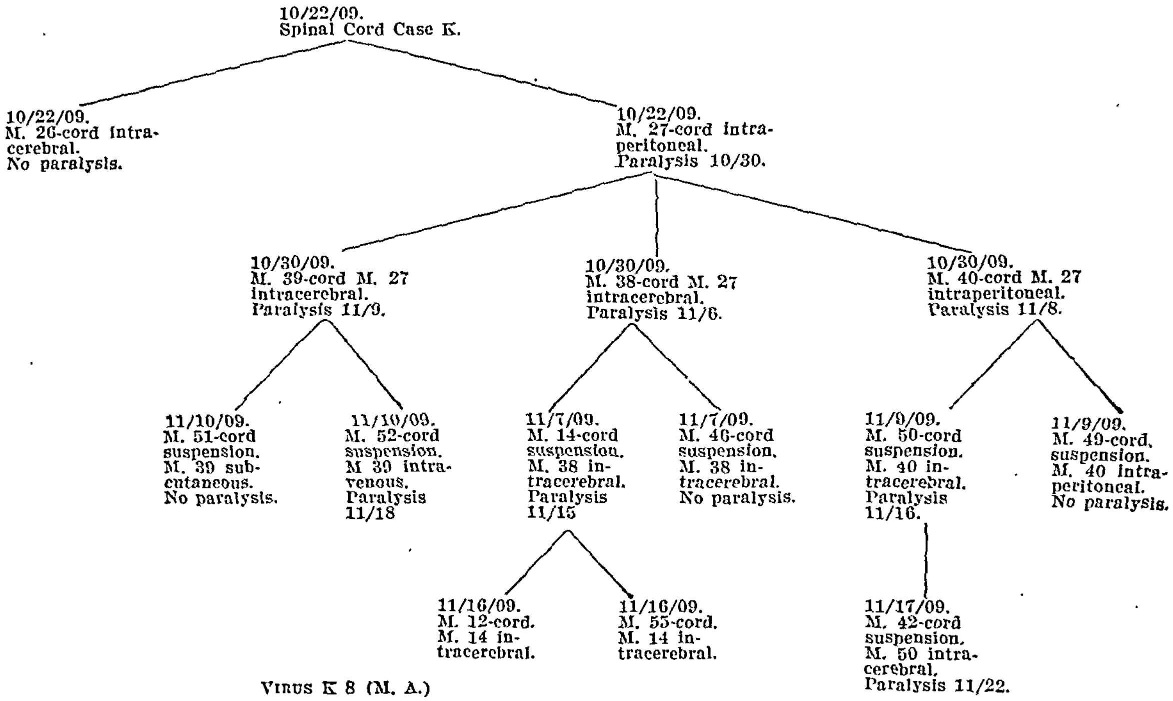
In a previous communication[1] we presented in the form of a chart the results secured up to that time in producing poliomyelitis in monkeys by injecting intracerebrally a virus, denominated M.A., obtained from the spinal cord of a child suffering from epidemic infantile paralysis. The virus had been passed successively through three generations of monkeys and is still being transmitted.

We desire in this communication to present the results in the form of a chart[2] obtained up to this time with the second virus, denominated K. It is, in our opinion, desirable that the facts thus far secured relating to this virus be published, since they extend considerably the previous observations.

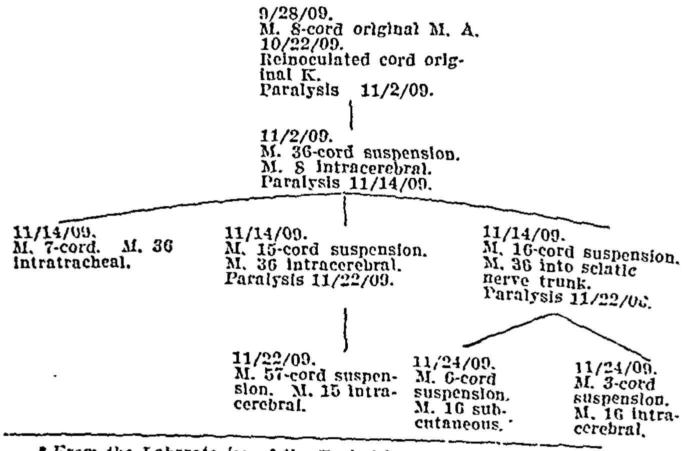
In the first place, it can now be affirmed that the virus of poliomyelitis *cannot be very difficult of transmission* to monkeys under the conditions leading to the development of the lesions and symptoms characteristic of epidemic poliomyelitis in man, since both specimens of human cord furnishing the original virus have sufficed for the transmission of the disease successively.

In the next place, it can now be stated that it is not absolutely essential that the virus be introduced into the brain, but that successive transmission is possible by way of the peritoneal cavity (Monkeys 27 and 40), by intravascular injection (Monkey 52), and by intraneural injection (Monkey 16). The lesions in the monkey in which the virus was introduced into the sheath of the sciatic nerve developed first on the side inoculated and later extended to the opposite side of the spinal cord.

On the other hand, it cannot yet be affirmed that still other avenues do not exist for the entrance of the virus into the central nervous system. Additional observations are required and are, indeed, in process of being made, before the statement can be ventured that infection does not occur by way of the skin, the respiratory passages and the digestive tract.



Virus K 8 (M. A.)



The conclusions to be drawn from the experiments related are to the effect that the virus of epidemic poliomyelitis is readily transmissible from man to monkeys and from monkey to monkey, by way of the brain, the peritoneal cavity and the circulation, and that, however transmitted successfully, it becomes established in the spinal cord and medulla, where it sets up characteristic lesions which are followed by equally characteristic effects that exhibit themselves as the usual symptoms of infantile paralysis in human beings.

Moreover, it can now be stated that this experimental form of poliomyelitis in monkeys is a severe and very often a fatal disease, and when recovery from the disease takes place there persist residues of paralysis which resemble the paralytic effects also persisting in human subjects of poliomyelitis.

THE SUBMUCOUS RESECTION OF THE NASAL SEPTUM

A RASPATORY FOR THE AVOIDANCE OF PERFORATIONS

OTTO T. FREER, M.D.
CHICAGO

Perforations in the course of submucous resections of *deflections of the nasal septum are, in my experience,* oftenest made during the denudation or excision of the bony part of the deflection after the removal of its cartilaginous portion. Nearly all of these perforations occur in baring the so-called ridge of its periosteal coverings, the term "ridge" being used to describe the bony wall which, arising from the nasal floor, forms the base of the septal skeleton and is composed of the incisor crest, anterior end of the vomer and superior maxillary crest. The ridge may be so low that it is barely indicated, or it may form a bony partition whose height may even reach five-eighths of an inch. When the septum is deflected into one or the other nostril, the ridge bends over into the naris of the convexity of the deviation in a varying degree, so that in extreme cases it may lie almost flat on the nasal floor. The periosteum covering the ridge is commonly firm, thick and vascular and envelops its upper border, crossing over it into the other nostril. The periosteal envelope of the ridge is, *therefore,* distinct from the perichondrial envelope of the cartilage of the septum, but perichondrium blends with periosteum along the top of the ridge, which thus marks the place where both perichondrium and periosteum of one side are continuous with *these membranes on the other side of* the septum. For this reason, after the removal of the cartilaginous deflection, the upper boundary of the ridge is not seen as bare bone, but is usually invisible under its covering of periosteum and has to be found by feeling with a probe. Observation has shown me that the difficulty so created in finding the ridge and resecting it, thus buried in adherent fibrous coverings, has made many operators afraid to touch it, so that they content themselves with merely removing the cartilaginous part of the deflection. Such neglect to take away the ridge is, in my experience, nearly always the cause of an imperfect clearing of the obstructed nostril. In several instances, when the space gained by a cartilaginous resection seemed sufficient, I have had to remove the ridge in a later operation, and I have known other surgeons to have the same experience. Even when it merely *takes up space* because of excessive thickness and is hardly bent over, the ridge should always be removed, as the breathing-space thus obtained is of the greatest advantage to the patient.

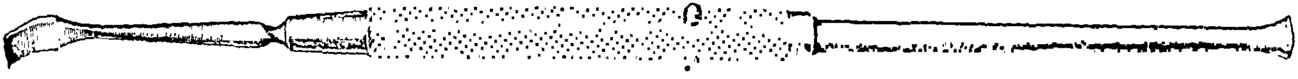

Fig. 1.—Raspatory for the denudation of bony deflections of the nasal septum.

The perforations referred to are made along the upper limit of the ridge, the operator, after successfully removing the cartilaginous deflection, tearing or cutting his way into the other nostril in attempting to free the bone from its periosteum along the upper border of the ridge and on the side of it which lies in the naris of the concavity of the deflection, the perforation occurring so easily that the surgeon does not know that he has made it until he looks through it into the other nostril. As *the upper boundary of the ridge represents* the bottom of the groove of the concavity, the perforation is seen in this bottom, when looking into the nostril containing the hollow of the deflection. The mucous membrane seems to tear with especial readiness in this region, so that *what seems a mere slit at first usually becomes a large* hole when the ridge is resected. While I succeeded in avoiding perforations in all but the rarest cases in this region in my earlier work, I never felt entirely sure that one would not be made until I began to bare the ridge with the little raspatory here described, which gives me a feeling of security in preparing the bony deflection for resection that I never had before I began to use it. This raspatory (Fig. 1) is a small chisel-edged instrument whose blade is curved on the flat, and has a front and lateral cutting edges.

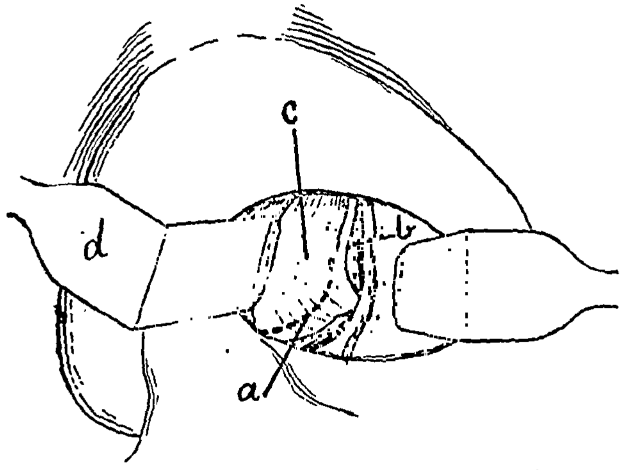

Fig. 2.—The left nostril, held open with retractors; the dotted line, a, shows the *incision which splits the periosteum along the* upper border of the "ridge;" b, cut edge of the uplifted mucous covering of the posterior part of the deflection; c, the mucous membrane of the opposite nostril (naris of the concavity of the deflection) uncovered by the removal of the cartilage; the retractor (d) holds the anterior (reversed L) flap forward.

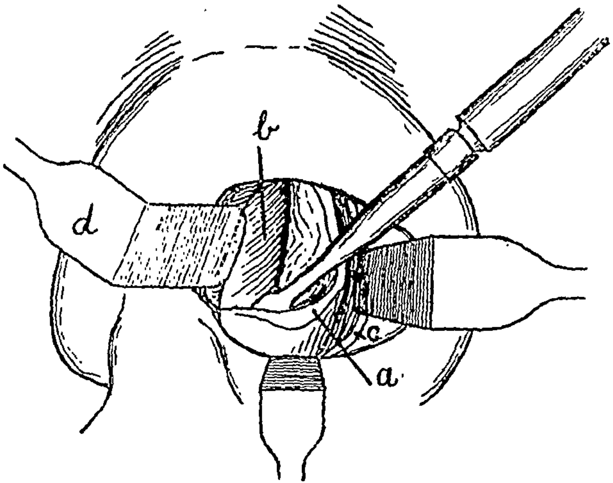

Fig. 3.—The left nostril held open with retractors; the entire bony deflection including the "ridge," a, has been bared of its *coverings by the raspatory, which may be seen working* toward the nasal floor on the concave side of the deflection; b, mucous membrane of the opposite nostril uncovered by the removal of the cartilage and uplifted from the bony deflection; c, cut edge of the uplifted covering of the posterior part of the deflection held away with a long retractor; d, retractor holding forward the anterior (reversed L) flap.

It is used in the following manner: After finding the upper boundary of the ridge with a dull elevator, the periosteum is split along this boundary from behind forward (Fig. 2) with a small round-edged knife of my set[1] designated by the capital letter E. The raspatory (Fig. 3) is then grasped firmly, close to its cutting end, so that it may not slip, and the periosteum is scraped away from the bone with it on the side of the convexity of the deflection. Then the denudation of the side of the ridge in the naris of the concavity is begun. Often the upper border of the ridge is found surmounted by a strip of cartilage contained in the periosteum envelope of the ridge, not the envelope of the cartilage of the septum, and this cartilage has to be scraped away with the raspatory from the ridge before the upper boundary of the bone can be found. Then the raspatory is made to work its way cautiously over the top of this boundary and down the other side of the ridge into the naris of the concavity until the bone is bared to the nasal floor (Fig. 3). In performing this denudation the instrument is held so that its long diameter is nearly across the direction of the ridge. After the incisor crest and anterior portion of the ridge are thoroughly denuded to the nasal floor, the raspatory is directed backward into the concavity of the bony deviation formed by the meeting of the deflected perpendicular plate of the ethmoid bone above and the vomer below, the angle made in bony deflections by the junction of these two bones forming a horizontally placed bony V, described by me in previous articles. The advantage of the raspatory over the ordinary sharp and blunt elevator in denuding the bone lies in the constant contact of the cutting edge with the bony surface, so that plunging or unexpected cutting through the coverings by the instrument is avoided, while in distinction to this, the elevator is inclined to leave the bony surface at some point, especially in hollowed places, and so is liable to cut through the mucous membrane.

34 Washington Street.

THE PRESENCE OF TUBERCLE BACILLI IN THE CIRCULATING BLOOD *

MAZYCK P. RAVENEL, M.D.
Professor of Bacteriology, University of Wisconsin; Director of State Hygienic Laboratory, University of Wisconsin
AND
KARL W. SMITH
Bacteriologist, State Hygienic Laboratory, University of Wisconsin; Instructor in Medical Bacteriology, University of Wisconsin
MADISON, WIS.

It has been known since the early days of bacteriology that tubercle bacilli are occasionally found in the circulating blood of patients suffering with tuberculosis. It is probable that every case of advancing tuberculosis is, at some stage of the disease, a bacteriemia; at least, there are times during the progress of every case in which tubercle bacilli can be found in the blood. This has been demonstrated by experiments and is also shown by those cases of miliary tuberculosis in which every organ of the body becomes simultaneously the seat of numerous tubercles.

The question was studied experimentally many years ago by Nocard, Bang, and others in an attempt to discover whether or not the flesh of animals suffering with tuberculosis was dangerous as food. The experiments carried out at that time showed that tubercle bacilli, although introduced directly into the circulation in large numbers, are in a very short time filtered out from the blood. It is universally believed that this action takes place in the lung, of which there is much experimental proof, because the muscular tissue is found free from bacteria, which could not be the case if it took place in these tissues, or if the blood still contained the germs. Much interest was caused, therefore, when in the fall of last year Dr. Rosenberger announced that tuberculosis was always a bacteriemia before it became localized in the various organs of the body, and that bacilli could be demonstrated in the blood by a very simple procedure. His method consisted in drawing from .5 to 10 c.c. of blood into a citrate solution in an ordinary test-tube, which was then placed in an ice-box for twenty-four hours, and the sediment examined without centrifugation. The ordinary stains were used, although Dr. Rosenberger recommended Pappenheim's stain as a decolorizer. In his first paper he speaks of the large number of tubercle bacilli which are sometimes found in a single field. This at once excited skepticism in the minds of many, as it seemed improbable that such masses of bacteria could pass through the capillaries. The alleged discovery was of such vast importance that it merited careful investigation.

Through the kindness of Dr. J. W. Coon, superintendent of the Wisconsin State Tuberculosis Sanatorium at Wales, we were allowed to obtain specimens of blood from a number of the patients known to be suffering with tuberculosis. At our first visit we drew specimens from eighteen patients, following Rosenberger's methods throughout exactly. After allowing the specimens to stand in the ice-chest for twenty-four hours we made smears from the sediment and stained and examined them. We then took the remainder of the blood and put it in a powerful centrifugal machine, and again made smears from the sediment. In all eighteen cases our results were absolutely negative by both methods. It will be observed that our second method, namely, examining smears after centrifugating 10 c.c. of blood, gave us a very much better chance of discovering any tubercle bacilli which may have been in the blood than the former method. We had intended pursuing the experiments on a larger number of patients, but private advices from several laboratories giving results identical with our own convinced us that it was useless. Further investigation may force us to change our opinion, but at the present time we feel justified in saying that the method of Rosenberger is not a reliable one and does not furnish a means for the diagnosis of tuberculosis either in the early stages or later.

NOTE.—Since the above paper was read the question of tubercle bacilli in the blood seems to have been entirely cleared up. Brem has shown that the acid-fast bacilli, mistaken by Rosenberger for tubercle bacilli, are frequently contained in distilled water as found in laboratories. After spreading the blood on the slide, Rosenberger lakes it by flooding with distilled water, which must stay in contact with it for some time, after which it is dried and stained. During the process of laking the acid-fast bacilli become fixed in the smear and take the subsequent stain. The observation of Brem has been confirmed by numerous workers, and at the present time we can say with a great degree of confidence that tubercle bacilli cannot, as a rule, be found in the circulating blood. Even when introduced directly into the circulation of animals, they disappear from the flowing blood within a few minutes, as has been demonstrated by Schroeder and Cotton, MacFarland, Anderson and others. We therefore feel confident in reiterating the opinion expressed by us in our presentation before the Wisconsin State Medical Society last June.

CASE OF DERMATITIS HERPETIFORMIS FOLLOWING PAPAW POISONING

B. G. R. WILLIAMS, M.D.
PARIS, ILL.

The following report is interesting mainly because of the apparent etiology of the disease:

History.—Mrs. K., American, aged 45, housewife, health previously good, stated that on the evening of September 18 she handled and smelled some papaws. In the morning an eruption appeared on her body, which she supposed was due to these as she had been affected previously in the same way. She used the ordinary sugar-of-lead lotion, but as there was no improvement in a week (September 26) she called on me.

First Examination.—In general this verified the patient's supposition as to the cause and showed the following condition of the skin: On all portions of the body except the hands, forearms, face, back, legs and feet were many small round vesicles filled with fluid. These were of various sizes, but always small and were round and surrounded by a marked hyperemia. Except for an almost intolerable itching and burning, there were no symptoms. I diagnosed the case as papaw poisoning and advised simple lotions, predicting most probably a speedy recovery.

The progress of the case, however, was not favorable, and on the evening of September 29 the patient informed me that she thought more eruption was appearing, especially on the back. She stated that the character of the eruption did not seem to have altered.

Second Examination.—When I saw her two days later (October 1) I was at once willing to change my diagnosis. Here and there over the skin were drying vesicles showing almost a scar-like character. I was struck at once by the appearance among many of them of a brown pigmentation, the intensity of which, though variable, was often very marked. Here and there were clumps of vesicles with injected bases. These I examined with a double convex hand lens. There were no ulcers nor were there any tendencies to spontaneous rupture. Vesicles, though still varying in size, were somewhat larger than previously. In general they were irregular in shape, often quadrilateral. Intermingled with the vesicles, hyperemia and pigmentation were scales showing the remains of dried vesicles. Blood examination showed no eosinophilia. I diagnosed a vesicular form of dermatitis herpetiformis. I prescribed mercury succinimid in small doses internally as an alterative and gave the patient resorcin-sulphur ointment for external application.

On October 3 practically the same condition was present. The distribution was as follows: neck, arms, flexor side of forearms, chest, back of trunk and on the thighs.

On October 20 the condition was the same except that the eruption was not so extensive. New groups of vesicles identical with the preceding ones appeared from time to time. Where clothing rubbed the body the lesions assumed an eczematous character. Pigmentation marked dying vesicles and slight scars showed the location of the oldest ones.

More Care for Swine than for Men.—The mere question of preservatives and adulterants is only a part of the great question of pure food to which the public must be educated, writes Professor Irving Fisher in a popular article in the New York *Christian Advocate.* We must not forget, for instance, the lack of proper meat inspection for the citizens of this country. The present federal meat inspection is almost wholly for the benefit of foreigners. Efficient state and municipal inspection is needed. Similarly we need a far better protection against an impure milk supply. In at least one of our states, the swine are better protected than the people. In that state the law requires that the skim milk from dairies shall be sterilized before it is fed to hogs, but there is no law requiring the sterilization of the remainder of the same milk which is to be made into butter and cream for human consumption.

Therapeutics

RENAL COLIC

Attacks of renal colic come on so suddenly and so unexpectedly, the pain which accompanies them is so agonizing, and the liability to subsequent attacks is so great, that suggestions concerning their prevention are certain to command attention, and the *New York Medical Journal,* Sept. 25 and Oct. 2, 1909, offers several articles on this phase of the subject.

It is not necessary to describe the well-known treatment for the paroxysm, but the following suggestions for the future management of the patient may be of value:

1. If the calculus becomes impacted in the ureter so that it cannot be dislodged, operation is necessary. If the calculus remains in the pelvis of the kidney, operation is advisable. If the calculus has caused purulent inflammation of the pelvis of the kidney, or abscess of the kidney, or if it has caused retention of urine, operation is immediately necessary.

It cannot reasonably be expected that remedies administered internally will cause the disintegration of a stone which is of sufficient size to set up an inflammation of the pelvis of the kidney, or is of sufficient size to permanently obstruct the ureter.

2. If the calculus is in the pelvis of the kidney, as shown by a radiograph, and is not causing any serious symptoms, and an operation is deemed inadvisable, the danger of its entering the ureter and causing an attack of renal colic will be diminished if the patient avoids muscular strain and unnecessary jolting.

3. If there is no reason to suspect that a calculus remains in the upper urinary passages, and if a calculus has certainly been passed, so that there is reason to believe that there exists in the patient a tendency to the formation of substances which will favor the development of renal calculi, a careful regimen should be laid down for his guidance.

Among the factors which are conducive to the formation of these calculi are intestinal fermentation and putrefaction, which give rise to autotoxemia, disordered metabolism, deficient oxidation and insufficient elimination by the intestines, kidneys, skin, and lungs.

The primary object of treatment, then, is to prevent the conditions from arising which either permit the formation of a calculus or will allow an increase in the size of one already present. As above stated, though a calculus may disintegrate, it should not be expected, and it is little less than reprehensible to promise, that any drug, or any water, will partially or completely dissolve it. However, both patient and physician hope to effect a solution, partial or complete, of calculi already formed, or, at least, that the sharp edges of the newly formed calculus may be rounded so that it will not cause so much pain. If a urate or phosphate concretion has not long been formed it may dissolve, but probably no other calculus can do so under the conditions surrounding it. The sharp edges of all calculi may become rounded, if long in the kidney, from mucous deposits alone.

The digestion must be made as nearly perfect as possible, and foods, drinks, and drugs that irritate the kidney must be prohibited. Intestinal fermentation must be avoided, and daily movements of the bowels must be secured. The diet should be carefully regulated, but the various articles allowed or forbidden vary according to the variety of calculus which the patient has passed, or it is decided is deposited in the urinary passages. If a calculus of uric acid has been passed, or there are uric acid crystals in the urine, as pointed out by Dr. John B. Talmadge, of New York (*New York Medical Journal*, Sept. 25, 1909), the patient should not take foods which contain large quantities of nuclein, such foods producing uric acid. The meats to be avoided are "liver, kidney, thymus, fish roe, caviar, smoked or pickled meats, and meat extracts." Talmadge would also prohibit "strong tea and coffee, asparagus, sugars, fats, farinaceous foods, and alcoholic beverages." He advises a diet "of meats which have been boiled to free them from the meat extractives, plenty of milk, eggs, bread, butter in small amounts, mild cheeses, jellies made with gelatin, and fruits in abundance, as the acids in these are not excreted as such by the kidneys."

If the concretions formed are uric acid or urates, uric-acid precursors, as above mentioned, should be avoided. Sugars, fats, and farinaceous foods need not be avoided as a class, though some individual starchy food may produce intestinal fermentation, and should be avoided. It is certainly best to reduce the frequency of the eating of meat to once a day, and it has been lately proved that alcohol in any form taken with a meal of meat tends to cause a decrease in the destruction of uric acid by the liver, or at least tends to cause an increased output of uric acid in the urine. Also, not all fresh fruits are advantageous, and cooked fruits are better than fresh fruits. Bananas, and especially roasted, are a valuable food. Prunes, especially cooked; oranges, if they agree with the individual; apples, if they agree, and especially cooked, are the fruits most satisfactory. Grape fruit is often inadvisable. Nuts (especially of the protein-fat type—almonds, peanuts, pignolias (pine nuts) —thoroughly chewed, are of value as food, and are generally readily digested.

It has lately been shown that potassium salts, such as the acetate, bicarbonate and citrate, tend to render the urine less likely to deposit urates and uric acid. This is not at all new clinically, but has only lately been demonstrated in the laboratory.

If the calculus passed consists of oxalate of lime or if oxalate of lime crystals occur frequently in fresh urine, the articles of food that should be especially prohibted, as tending to the formation of this salt, are, as enumerated by Talmadge, "spinach, rhubarb, beans, beets, tea, cocoa, gelatin, and all foods containing any great quantity of calcium (milk, eggs, vegetables of the cabbage family)." These foods, he states, contain a great deal of oxalic acid. The possibility of producing this substance from tea and cocoa is remote, and the amount that could be formed from beans is certainly small; hence these three articles of food could be allowed. Patients who have oxaluria should take "foods containing a high percentage of magnesium, as magnesium oxalate is easily soluble and thus oxalic acid is easily excreted." Such foods are "meat, fish, bread, farinaceous foods, and apples." Any of the magnesium salts also have this favorable chemical action in preventing the formation of calcium oxalate. Perhaps the best salt to administer is magnesium biphosphate (acid magnesium phosphate; the dose being 0.50 to 1 gram (7½ to 15 grains). If much is given it acts as a laxative.

If the calculus is phosphatic and the urine tends to deposit phosphates, the diet should consist largely of albuminous foods and foods containing organic acids. If much milk is taken, lactate may be administered at the same time, as it tends to keeps the phosphates in the intestines and prevents their absorption.

Nervous disturbances, pain, too much mental work, and worry will increase the output of phosphates, and such nervous tire should be prevented if possible.

Whatever the concretion may be that is deposited in the urine, oxidation and elimination should be promoted by general physical exercise, in the open air, and by bathing, especially warm bathing, and perhaps by other hydrotherapeutic or sweating measures.

The most useful medicinal treatments are the alkaline diuretics and the urinary antiseptics. Of the former class, potassium citrate, which is the pleasantest to take of the potash salts, should be administered in 1-gram doses (15 grains), every three hours, or in 2-gram (30-grain) doses, three or four times a day, preferably after meals. When taken with plenty of water it will, as above stated, aid in preventing uric acid and urate concretions. It is advisable, whatever may be the character of the calculi, that considerable quantities of water be drunk, preferably distilled water, as tending to aid in bringing about solution and keeping in solution the salts of the urine. It is often unwise for a patient to drink large quantities of an alkaline mineral water which may contain ingredients which are inadvisable for him to take into his system. It is also inadvisable to continue for any length of time alkaline salts in sufficient quantity to render the urine alkaline, as a prolonged alkaline urine tends to cause phosphatic deposits, tends to allow germs to grow, and mucous membrane irritation to occur in the urinary tract. Also a too long alkaline treatment is debilitating to the system; the loss of nitrogen is increased, and the weight is diminished. Alkalies tend to produce anemia, and iron must often be administered with the diet necessary to prevent uric acid deposits.

Of the class of urinary antiseptics, the one of most value is hexamethylenamin, which should be given in doses of from 0.25 to 0.50 gram (from 4 to 7½ grains), taken, dissolved, in a glass of water, three or four times a day.

If there is any pus in the urine or any infection is considered to be present, or an extra amount of mucus is produced, which tends so easily to form nuclei for depositions of salts in the urine, the best medicinal treatment is hexamethylenamina or phenyl salicylas (salol). If the urine is ammoniacal the patient should generally be given one of these drugs. Salol should not be administered if there is any kidney inflammation, or if there is albuminuria.

When there are urinary calculi, the condition of the circulation should always be carefully examined, and if there is any failure of the heart or any insufficiency of the heart muscle, or arteriosclerosis, large amounts of liquid should not be given, as the extra work put on the circulation is inadvisable. It is much better to overcome the tendency to the formation of calculi by a proper diet than by very large amounts of water under these conditions.

Tuberculosis in Children of the Tuberculous.—A. Pissavy has been collecting data in regard to the prevalence of tuberculosis in 569 households in France, some in towns and others in rural districts. In 469 of these households neither parent was tuberculous, but 123, that is, 8 per cent. of the total 1,428 children in these families acquired tuberculosis. In 100 other households one or both of the parents were tuberculous and 93 of the 292 children in these families contracted the disease, that is, about 31 per cent. The proportion of children contracting the infection averaged about the same in the country and town families. His communication was published in the *Bull. Soc. Méd. des Hôp.*, 1909, xxvi, 456.

SATURDAY, DECEMBER 4, 1909

THE PHARMACOPEIA, ITS HISTORY AND ITS IMPORTANCE TO THE MEDICAL PROFESSION

The importance of the next Pharmacopeial Convention should be thoroughly understood by all medical societies and physicians. These conventions, as well as the national Pharmacopeia, originated in a proposition submitted to the Medical Society of the County of New York by Dr. Lyman Spalding in 1817. Dr. Spalding proposed that the United States be divided into four districts—northern, middle, southern and western—and that each district should hold a convention of delegates from the medical societies and schools situated within it, to formulate a pharmacopeia. The four district pharmacopeias were to be taken to a general convention to be held at Washington, composed of delegates from the four districts. From the district pharmacopeias the delegates were to compile a national pharmacopeia. This plan was adopted, the district convention for New England being held in Boston and the convention for the middle states in Philadelphia, June 1, 1819. No conventions were held in the southern and western districts, but delegates to the national convention were appointed. The first general convention for the formulation of a national pharmacopeia met at Washington, Jan. 1, 1820. The two pharmacopeias prepared in the northern and middle districts were consolidated into one work, which was published in Boston, December, 1820, in both Latin and English. A second edition appeared in 1828.

The convention of 1820 provided for its own perpetuation and for future revisions, by instructing its president to issue notices in 1828 to all incorporated state medical societies and incorporated medical colleges and schools, asking each to vote for three delegates to represent the district at the general convention to be held at Washington in January, 1830, the convention to consist of twelve delegates. The second convention was held at Washington on Jan. 4, 1830, thirteen delegates being present. It provided for its perpetuation by instructing its president to issue a notice to incorporated state medical societies, incorporated medical colleges and incorporated colleges of physicians and surgeons, asking each to elect three delegates to attend a general convention to be held at Washington in January, 1840. The district plan of representation was given up and has never been resumed.

At the third convention, held in 1840, twenty delegates were present. A committee on revision and publication was appointed which published the second revision of the Pharmacopeia in 1842. This committee was instructed to ask the cooperation of schools of pharmacy in its work.

In the call for the fourth convention of 1850, incorporated colleges of pharmacy were included and were allowed to send three delegates, the same as medical colleges. This convention, which met at Washington in May, 1850, was composed of thirty delegates. Only two pharmaceutical schools were represented, all of the other delegates being from medical colleges and societies.

In 1860 the fifth convention was held, thirty delegates being present, four colleges of pharmacy being represented.

The sixth convention was held May 4, 1870, sixty delegates being present, seven pharmaceutical schools being represented. The fifth revision was published in 1873.

The seventh convention met May 5, 1880. One hundred and nine delegates were elected to represent ten medical societies, twenty-three medical colleges, eleven pharmaceutical colleges and the medical departments of the Army, the Navy and the Marine-Hospital Service. Seventy-five delegates were present.

The eighth convention was held on May 7, 1890, 175 delegates being present, representing fifteen medical societies, twenty-three medical colleges, twenty-five pharmaceutical associations, twenty-three colleges of pharmacy and the medical departments of the three government services. The provisions made for representation in 1900 were the same as those for 1890.

The ninth decennial convention was held at Washington May 2, 1900. Forty-one delegates were present representing twenty-six medical societies, forty-four delegates from thirty medical colleges, fifty-three delegates from twenty-seven pharmaceutical colleges and fifty-seven delegates from twenty-eight pharmaceutical societies, the American Medical Association, the American Pharmaceutical Association and the three government services being represented by twelve members. The total attendance, as shown by the official report, was two hundred and seven, of which one hundred and fourteen were pharmacists and ninety-three were physicians.

The point to be emphasized in the above historical summary is that the convention was originally inaugurated and for many years carried on solely by the medical profession, and that it was not until 1850 that other than medical societies and medical colleges were authorized to send representatives. In that year, pharmaceutical colleges were for the first time given representation. Not until 1890 were pharmaceutical societies added to the list of accredited bodies.

The medical profession during the past thirty years has not given to the revision of the Pharmacopeia the attention which its importance deserves. In spite of the fact that this book originated with the medical profession and was compiled and published primarily for its use, it has come to be regarded too much by physicians as a book which is of interest and value mainly, if not solely, to the pharmacist and in which the physician is not especially concerned. The attitude of the physician toward the Pharmacopeia as well as the lack of knowledge on this subject has been frequently commented on in THE JOURNAL. It is now time that specific and lasting reforms were effected. Two definite steps should be taken before the meeting of the next convention in Washington: (1) All incorporated state medical associations and medical colleges entitled to representation should select the three best representatives possible and should see to it that they attend and take part. (2) Each county society should devote at least one meeting during the winter to a discussion of the present Pharmacopeia and the formulation of suggestions as to its improvement.

There is, indeed, grave danger lest this work, which was primarily a reflection of the needs of the medical practitioner, should become a purely pharmaceutical rather than a medical compilation. There is also danger of its being controlled by commercial interests. Such a result will be due solely to lack of interest and activity on the part of the medical profession. Active interest in this matter should be aroused and medical societies should see to it that they are properly and effectively represented in the coming convention, and that their delegates are instructed regarding the desires and opinions of those they represent. If every county society will devote one evening to the discussion of this question and will send its recommendations to Dr. Reid Hunt, chairman of the Committee of the American Medical Association on the Pharmacopeia or to the Council on Pharmacy and Chemistry of the American Medical Association, their recommendations will be transmitted to the convention and will receive consideration.

ARTHRITIS DEFORMANS

Nothing in medicine is more obscure than the pathogenesis of the chronic joint disturbances which we group, in order not to commit ourselves, under the descriptive term "arthritis deformans." One of the essential causes of our ignorance concerning them is a lack of thorough and extensive study of the anatomic changes which underlie the clinical manifestations, which is undoubtedly due in large part to the difficulty one meets in obtaining any considerable quantity of material of this sort. An extensive study of material from sixty-five cases, collected during eight years by Nichols and Richardson,[1] promises to clear up many of the misunderstandings and to furnish the sound anatomic basis which we must have before the etiology (and, depending on that, the therapy) can be worked out.

On account of the close relationship of the several kinds of tissues which make up the joints, it is possible for the same irritant to produce many different kinds of structural changes according as it acts on one or the other of these tissues; or, on the other hand, various agents may produce quite similar changes in the joints. As a matter of fact the lesions found, irrespective of what the clinical features or apparent etiology may have been, fall distinctly into one of two categories, proliferative and degenerative. It being a general law of pathology that the same agent may cause either proliferation or degeneration, in accordance with concentration, tissue nutrition, and other factors, it follows that these two pathologic groups do not correspond to two different sets of etiologic factors or to two different diseases, but merely represent different effects from similar causes, or similar effects from different causes. Clinically, however, there are well-marked differences, corresponding to the degenerative and proliferative types of joint changes, when either of these types occurs in a sufficiently distinct way.

The proliferative joint changes usually predominate in the cases of arthritis which begin rather acutely, resembling acute rheumatism at first, and involving more often persons under 50 than older, and the clinical course is characterized by attacks and remissions of the joint symptoms, often terminating in complete ankylosis. With the pronounced degenerative type of lesions is commonly associated a history of insidious onset, usually affecting older people, and causing great anatomic alterations in the joints with but little tendency to produce actual ankylosis. But, since the presence of proliferative changes in one part of a joint may cause degenerative changes in another part, or conversely, it is evident that both anatomic changes and clinical manifestations are often of mixed character. It is also evident that, once the injury in the joint has been started, a vicious circle is readily established, for a primary degenerative change may start up proliferative processes in the neighborhood, and, these causing degeneration of opposed surfaces, the process becomes progressive; hence the bad prognosis of arthritis deformans and the mixed anatomic picture which has caused so much confusion of classification and pathology. Once the joint injury has become well established, therefore, the pathologic changes may continue even when the original etiologic factor has disappeared, and when this factor is a chronic persistent one the course of the disease must necessarily be downward. In earlier stages the prognosis is better if the exciting cause can be removed, and hence the importance of establishing the etiology of the joint changes. As already intimated, we are commonly at a loss as to etiology, partly because of previous lack of understanding of the pathology, and partly because of the extremely varied causes which may start up joint changes that eventually terminate in chronic arthritis. Nichols and Richardson believe, from their studies, that there is no one specific cause, as some have maintained, but that the same anatomic results may come from the most different causes. Sometimes acute infection begins the joint changes, sometimes chronic trauma, but more often, in all probability, some soluble irritant, presumably of metabolic origin, selectively affects the joints and adjacent bone tissue. With the careful study of the pathology which these authors have supplied for a basis, the search for the etiology should now make more substantial progress than it has heretofore realized.

---

SUDDEN DEATH DURING ANESTHESIA

Although we have not yet ascertained the nature of the chromaffin substance which Kohn found in the adrenals and other related organs of sympathetic origin, yet that it is of essential importance to the function of these organs is unquestionable, for its presence and quantity stand in direct relation to their functional capacity. For example, Wiesel found that in Addison's disease there was an absence or paucity of the chromaffin substance not only in the adrenals, but also in the other organs of the so-called chromaffin system. Conversely, in cases of destruction of the adrenals by malignant growths without resultant Addison's disease, it has been found that the chromaffin cells in the other organs were well supplied with their specific content, thus explaining why destruction of the adrenal had not resulted in the familiar symptom-complex of Addison's disease. These and other observations indicate that the amount of chromaffin substance present in the tissues is an index of their functional capacity; and this permits of study of the relation of these tissues to various disease processes.

At the present time the chief property which can be ascribed to the chromaffin system is that of stimulating vascular tonicity; and Hornowski, struck by the similarity of the conditions presented by persons dying suddenly during or after surgical anesthesia, to the manifestations of shock, which is essentially a loss of vasomotor tone, began an investigation of the condition of the chromaffin system in death following operations. In four such cases he found constantly a decrease in the chromaffin substance,[1] and he was able to cause a similar reduction in the chromaffin substance experimentally in rabbits by prolonged or repeated anesthetization. This effect he ascribes chiefly to the action of the chloroform, explaining it as follows: Chloroform lowers the blood-pressure, and the chromaffin system is stimulated to neutralize this decreased vasomotor tone; if the stimulation of this system is too violent or protracted, or if previous shock, trauma or infection have injured or overworked the chromaffin cells, they become exhausted and unable to replenish the supply of vasostimulating substance, death resulting from vasomotor paresis. In such cases microscopic examination shows a striking absence of chromaffin substance in the usual locations, whereas when no vascular paresis results from anesthesia and operation, because of adequate compensation by the chromaffin cells, the brown color of this tissue is very pronounced on account of the quantity of stored chromaffin substance.

Schur and Wiesel have also found that the chloroforming of rabbits decreases the staining of the chromaffin cells by chromic acid, and they, too, suggested that this effect of chloroform may account for sudden deaths during anesthesia. Hornowski shows, in addition, that surgical trauma, previous injury or pain, and infection also have a similar effect, so that the exhaustion of the chromaffin system during anesthesia may be more properly ascribed to the added influence of these causes, the chloroform by its depression of vascular tone completing the depletion of blood-pressure-raising substance. Although Schwarzwald[2] and others have not always found demonstrable decrease in chromaffin material in all persons dying during anesthesia, yet the positive results of experiments and the positive autopsy findings that have been recorded are sufficient to indicate the possibilities of this line of research. An interesting observation made some time ago by Hedinger[3] carries support to Hornowski's theory. He found that in status lymphaticus, in addition to the lymphatic hyperplasia, there is a marked hypoplasia of the chromaffin system, analogous to that seen in Addison's disease. Since the most striking effect of the status lymphaticus is sudden death following trivial shock or trauma, this deficiency of the chromaffin system is significant; furthermore, not a few deaths in status lymphaticus have occurred during anesthesia.

THE VALUE OF INDEXED CASE RECORDS

To those who are unfamiliar with the advantages of a system of classifying and indexing case histories the keeping of such records may appear like an entirely unnecessary and laborious piece of work. If the habit is once formed, however, it will be found to be of the greatest help in clarifying the worker's conception of the field in which he is working, and an incentive to more precise observation. If an effort is made at regular intervals—once a week, for example—to record in black and white the diagnosis of every case that has been seen during that interval it will afford a very interesting and instructive review, and the perspective thereby gained will not infrequently serve to clear up obscure points and to suggest practical points as to prognosis and treatment as well as diagnosis. If the observer is thoroughly honest with himself and takes refuge in no obscure terms or uncertain diagnoses it will inevitably be found that in a fair proportion of his cases a decision must be definitely or indefinitely postponed. Necessary data will be found wanting in certain cases; diagnostic points which have been overlocked and which might throw light on the problem come to mind, with the result that at the next interview with the patient these points will be noted and the condition will be better understood. As the records grow, their value will be constantly increased by a properly made index, rendering early material available for study and comparison with recent cases. This advantage of the index will be enhanced if, besides the record of diagnoses, there is kept an index of signs and symptoms. While such an indexed record would necessarily be voluminous, it could be kept within bounds by recording only the important and unusual phenomena, while the observer could accumulate data on any particular subject in which he was interested to the limit of his material and time. An outline of a system for classifying and indexing case records was published in THE JOURNAL early this year.[1]

[1] Hornowski: Virchow's Arch. f. path. Anat., 1909, cxcviii, 93.

[2] Schwarzwald: Verhandl. d. deutsch. path. Gesellsch., 1909, xiii, 269.

[3] Hedinger: Verhandl. d. deutsch. path. Gesellsch., 1907, xi, 29.

So far as the question of time is concerned, the actual work of writing requires far less than might be imagined, and the time spent in thinking over the problems which present themselves is far better spent in this way than in unsystematic study of abstract problems. Besides the advantage of obtaining a clearer and more intimate knowledge of the individual patients which is afforded by such a review, there is much interest and profit in grouping the various conditions and comparing the features which serve to distinguish the different groups. Certain pathologic conditions may be found to be associated in a number of instances with subsidiary or secondary processes, which may or may not be emphasized in familiar literature; but such a personal observation would be of far more value to the practitioner than could any familiarity with the published opinions of others. Suggestions of this nature frequently present themselves in a study of groups of cases, and in turn serve as a potent stimulus to more thorough observation of the individual patients. The same association will be looked for in new patients presenting one or the other of the conditions noted, the suggested hypothesis being proved or disproved as the series is enlarged. In short, such a system places the "experience" of the observer on a foundation of relatively certain facts, instead of on the vague impressions which so often constitute the basis of authority.

It may be asserted with some truth that there is danger of being misled by reliance on an insufficient amount of evidence, but, as every worker must trust to some extent to his own observations, it is just as well that he should have as exact a knowledge as possible of what his own observations really are. This exact knowledge is no more reason for the student's being intolerant of the experience of others than ideas based on a less certain foundation would be. It should be needless to add that any notes embracing data from the misty side of the region that separates the known from the "guessed at" are worse than useless.

ALTMANN'S GRANULES IN TUMOR CELLS

Some time ago it was shown by Altmann that the glandular cells of vertebrates contain well-defined granules which can be specifically stained with acid fuchsin, their number varying with the nature and functional activity of the cells examined. These granules are most commonly called "Altmann's granules," but also "fuchsinophil granules" and "plasmosomes." Similar but smaller granules have been described in plasma cells and lymphocytes by Schridde. A study of the distribution of these intracellular granules in human tissues in normal and pathologic conditions, including particularly tumors, has been made by Beckton, with interesting results which may prove to be of much practical importance.[1] He finds that the granules of the glandular epithelium are probably different from those of the stroma cells, as the former can be fixed by formalin, while the latter are fixed only by bichromate solutions. The presence of abundant granules of the latter type in plasma cells, lymphocytes and fibroblasts supports the contention that these cells have a secretory function, since Altmann's granules are supposed to have to do with secretory activity.

In inflammatory conditions these cells, as well as the proliferating endothelial cells, are found to contain abundant granules, whether the process is acute or chronic. In tumors, however, a suggestive observation was made, namely, that in malignant tumors of all kinds the Altmann granules are absent from the cancer cells, or else are scanty, while in benign tumors they are present in much the same proportion and form as in the normal tissue which the tumor replaces. The importance of this finding lies in two directions: first, it may point the way to an improvement in our differential diagnosis of malignant tumors from benign tumors and from inflammatory conditions; second, it has suggestive bearing on the biology of tumor cells. Thus, as Lazarus-Barlow points out, the absence of Altmann's granules from cancer cells shows that such cells are fundamentally different from the normal cells from which they arose. This difference may be regarded as an expression of deviation from, or loss of, normal function.

If Beckton's observations are confirmed by those who repeat his work—and it will undoubtedly soon be repeated—the differential microscopic diagnosis of cancer will become much easier and more certain than it now is.

THE RESPIRATORY HIPPUS

A recent note by Roch and Campiche[1] calls attention to an unusual phenomenon, which they had previously described and designated as "the respiratory hippus." This phenomenon, which consists of an inspiratory dilatation and expiratory contraction of the pupils, has been noted also by Wiesenger[2] and by several Italian observers, but its significance is still a matter of doubt. In the cases seen by Roch and Campiche it was always associated with a pulsus paradoxus, and, in their opinion, might be explained on the same grounds, namely, an abnormal respiratory variation in blood-pressure due to unusual variations in the intrathoracic pressure, especially when associated with myocardial weakness.

Medical News

GEORGIA

District Society Meetings.—The Fifth Congressional District Medical Society held its fifth annual meeting in Atlanta October 5. The session was devoted to the discussion of pellagra. The following officers were elected: President, Dr. Hugh M. Lokey, Atlanta; vice-president, Dr. William D. Travis, Covington, and secretary-treasurer, Dr. J. Ross Simpson. Atlanta.——The Tenth District Medical Society, at its annual meeting, held in Augusta, November 9, elected the following officers: President, Dr. Noel M. Moore, Augusta; vice-president, Dr. Joshua R. Beall, Blythe; secretary-treasurer, Dr. George A. Traylor, Augusta; and district councilor, Dr. Wyman W. Pilcher, Warrenton. The principal address was delivered by the president-elect on "Pellagra."

ILLINOIS

New Hospital for Sterling.—The charter for the Whiteside Public Hospital, Sterling, has been applied for and is expected to be granted in a short time. The prospects for the success of the institution are excellent, as both the laity and physicians of the city are interested in the project.

Physicians' Club Organized.—A club has been organized in Lewistown, whose membership comprises all the physicians in the city. The following officers have been elected: Dr. D. D. Talbott, president; Dr. Eli G. Davis, vice-president; Dr. William S. Strode, secretary; and Dr. Samuel Oren, treasurer.

Personal.—Dr. William E. Washburn, Kewanee, received internal injuries in the overturning of his automobile at Cherry, November 21.——Dr. Charles E. Colwell, Aurora, has been elected president; Dr. Oliver H. P. McNair, Batavia, vice-president, and Dr. R. S. Denney, Aurora, secretary-treasurer of the Aurora Hospital.

The New Cook County Infirmary.—All of the buildings of the new Cook County Infirmary, on which work was begun last spring, are under roof, and the present indications are that the institution will be ready for occupancy by the middle of January. The institution, when completed, will have cost $1,750,000, and will accommodate about 1,800 inmates, with ample provision in the general scheme for the erection of additional buildings as required. On the highest spot on the grounds has been built the hosiptal for tuberculosis patients, 300 feet away from the nearest building of the central group.

Chicago

Cornerstone Laid.—The cornerstone of the addition to the Norwegian Lutheran Deaconess Home and Hospital was laid November 25. The new building is to cost $75,000.

Explosion in Hospital.—An explosion in the furnace of the American Hospital, November 28, wrecked the heating plant and created much alarm. The patients in the building escaped injury, as the physicians and nurses were promptly on hand and prevented a panic.

Certified Milk in Chicago.—Dr. Charles S. Bacon, in his illustrated talk on this subject in the Public Library building, November 27, spoke of the organization of the Milk Commission of the Chicago Medical Society, and stated that three country dairymen had been induced to sign contracts drawn up after the pattern of the national form, and had agreed to conform to the rigid demands of the commission. In return for this, the commission gives each dairyman a copyrighted trade mark bearing the certification of the society, which appears on the label or stopper of every bottle.

KENTUCKY

Personal.—Dr. Alexander Vertes, Louisville, has returned from abroad.——Dr. Matthias R. Perry, Russellville, has succeeded Dr. M. E. Alderson, Russellville, as physician of Logan county.

Society Election.—Hardin County Medical Society has elected the following officers: Dr. Clyde C. Carroll, White Mills, president; Dr. D. Elmo McClure, Sonora, vice-president; Dr. John M. English, Elizabethtown, secretary-treasurer, and Dr. C. T. Riggs, Upton, delegate to the State Medical Association.

Babies' Milk Fund.—The Babies' Milk Fund Association of Louisville, in its second annual report, showing the work done during the summer of 1909, states that at the beginning of last October the association had to its credit six distributing stations and one laboratory in operation; six graduate nurses, four assistants, four supervisors and one assistant supervisor on duty; twelve weekly consultations held; affiliation with eighty-two physicians; registration of 284 children; 2,300 visits made by nurses to homes; $2,900 collected and 34,000 bottles of milk distributed.

MASSACHUSETTS

New Hospital Opens.—The Rufus S. Frost Hospital, Chelsea, opened its new building informally, October 11, to the members of the medical profession and representatives of the state and city. The hospital is built on the site of the Rufus S. Frost homestead and is three stories in height, flanked with two-story wings. The right wing is devoted entirely to surgery, including a maternity ward; the left wing to medical wards and private rooms. There are seventy-eight beds in the institution. The medical and surgical staff is as follows: Chairman, Dr. E. Frank Guild; secretary, Dr. George B. Fenwick and Drs. Charles N. Cutler, Frank A. Mahoney, Francis B. McClintock, Edward J. Powers, Frederick H. Plummer, Frank S. Garrett, John M. Wells, Joseph B. Fenwick, John M. Doran and John G. McPhail, all of Chelsea; Drs. J. Stewart Morris and William C. Newton, Revere; Dr. Horace E. Bragdon, East Boston, and Dr. William J. Porter, Winthrop. The consulting staff consists of Drs. George H. Cunningham, Jr., George W. W. Brewster, LeRoi G. Crandon, Arthur T. Legg, Philip Hammond and Frederick M. Spalding, all of Boston.

MARYLAND

Concentration of Colleges.—Senator Linthicum proposes a concentration of medical and other colleges which receive state aid into a state university, to be governed by a board of regents.

Appropriations Asked.—The State Board of Aid and Charities has been asked for the following annual appropriations: College of Physicians and Surgeons, Baltimore, $5,000; Maryland Medical College, $4,000; Baltimore Medical College, $5,000; University of Maryland, $4,000; Medical and Chirurgical Faculty of Maryland, $10,000; and the Maryland Asylum and Training School, $50,500 for maintenance and $52,500 for new buildings.

County Society Election.—Queen Anne's County Medical Society, held its annual meeting at Centerville, November 12. The following officers were elected: President, Dr. Ernest F. Smith, Centerville; vice-president, Dr. James W. Stack, Wye Mills; secretary-treasurer, Dr. Laura E. Reading, Hayden; delegate to the Medical and Chirurgical Faculty of Maryland, Dr. Norman S. Dudley, Church Hill, and censors, Drs. William G. Coppage, Church Hill; Wesley W. Chairs, Queenstown, and Walter H. Fenby, Ruthsburg.

Baltimore

Goldberger Prize Awarded.—Dr. Clemens von Pirquet, Johns Hopkins University, has been awarded the Goldberger Prize of 2,000 crowns by the Imperial and Royal Society of Physicians of Vienna on account of his discoveries of certain phases of immunity and skin reaction in the diagnosis of infantile tuberculous lesions. This prize is awarded every three years for research work in experimental medicine.

New Buildings on Johns Hopkins Grounds.—The contract has been awarded by the Johns Hopkins trustees for the building of the Phipps Dispensary on the hospital grounds, at a cost of $500,000. The building will be five stories in height, fire proof and will correspond with the other buildings of the group.——The Harriet Lane Johnson Home for Crippled Children is to be erected on the grounds of Johns Hopkins University at a cost of $300,000.

---

[1] Roch, M., and Campiche, L.: Coexistence de l'hippus respiratoire et du pouls dit paradoxal. Rev. de méd., 1909, xxix, 661; abstr. in THE JOURNAL A. M. A., Sept. 18, 1909, liii, 979.

[2] Wiesenger: Charité Ann., 1904-05, xxx, 591.

Personal.—Dr. A. M. Foster, superintendent of the Eudowood Hospital for Consumptives, near Baltimore, has resigned, to take charge of the Louisville Antituberculosis Association and Municipal Tuberculosis Department.——Dr. Gustavus Charles Dohme is said to be critically ill with uremia.——Dr. Thomas H. Buckler, president of the Paint and Powder Club, has resigned.——Dr. Ira Remsen, president of the Johns Hopkins University, has been made president of the Charity Organization Society.——Dr. John S. Fischer sailed for Europe November 27.

MISSOURI

Tag-Days.—Hospital Tag-Day in St. Louis, November 27, is reported to have netted more than $30,000 for the hospitals of the city.——St. Joseph collected more than $7,500 for charity at its first tag day, November 21.

Antituberculosis League Formed.—The Louisiana Antituberculosis League was organized November 15. Dr. James W. Dreyfus was elected president, and Drs. Joseph B. Unsell a member of the executive committee.

County Society Meetings.—The Caldwell County Medical Society, at its annual meeting, October 27, elected Dr. Benjamin F. Carr, Polo, president; Dr. Stephen D. Smith, Cowgill, vice-president, and Dr. George W. Goins, Breckenridge, secretary-treasurer.——Howard County Medical Association, at its annual meeting held in Fayette, November 5, elected the following officers: President, Dr. W. B. Kitchen, Glasgow; vice-presidents, Dr. Thomas C. Richards, Fayette, and Joel Y. Hume, Armstrong; secretary, Dr. Charles W. Watts, Fayette; member of the house of delegates, Dr. Joel Y. Hume, Armstrong; and censors, Drs. Charles O. Lewis, Fayette, Andrew W. Moore, Fayette, and Vaughan Q. Bonham, Fayette.

State Bureau of Vital Statistics.—The State Bureau of Vital Statistics, which was provided for by the last legislature, and which is in charge of the state board of health, is now in process of organization, and will be in full operation January 1 next. Dr. Frank B. Hiller, secretary of the State Board of Health, is registrar for the central bureau. The law prescribes that each city and incorporated town shall constitute a registration district, and for the convenience of the rural profession of the state these sections will be divided into rural districts. All births and deaths must be reported to the local registrar, who in turn reports to the central bureau on the tenth day of each succeeding month. No burial or other disposition of a dead human body can be made without first securing a burial or transit permit from the local registrar. The certificate, in addition to the fact of death, will furnish statistics regarding mortality from various diseases, nationality, occupation, conjugal relation, age, sex, etc., also mortality by cities, towns, and rural districts. Missouri is said to be the first state in the Union to put into practical use the new United States standard death certificate.

NEW HAMPSHIRE

Medical Society Meeting.—The Rockingham County Medical Society held its fifth annual meeting in Portsmouth November 11. The following officers were elected: President, Dr. Elbert A. Landman, Plaistow; vice-president, Dr. Thomas W. Luce, Portsmouth; secretary, Dr. Walter Tuttle, Exeter; treasurer, Dr. Alice M. M. Chesley, Exeter; censor, Dr. John H. Neal, Portsmouth, and delegate to the state society, Dr. John W. Parsons, Portsmouth.

NEW YORK

State Board Approves.—The State Board of Charities has approved the certificate of incorporation of the Newburgh Tuberculosis Sanatorium which is to be the gift of former Governor B. B. Odell.——Approval has also been given to the consolidation of the New York Infant Asylum and the Child's Nursery. This consolidation, when ratified by the Supreme Court, will unite institutions whose joint resources are about $1,000,000, and whose annual expenditures at present are more than $200,000.——The incorporation of the Southampton Hospital Association, which proposes to establish a general hospital at Southampton, L. I., as well as the incorporation of the Lakeview Home, were approved by the board.

Bequests to Charities.—By the will of the late John S. Kennedy, $2,250,000 is devised to the Presbyterian Hospital, $25,000 to the New York Infirmary for Women and Children, and $10,000 each to the Manhattan Eye and Ear Hospital, the New York Orthopedic Dispensary, the Fordham Home for Incurables, and the New York Society for the Relief of the Ruptured and Crippled.——By the will of the late Mr. Mitchell Valentine, one-half the residue of an estate, after the payment of certain small bequests, is bequeathed to the Presbyterian Hospital. The value of the bequest is estimated at $1,000,000.——The will of the late Emanuel Einstein bequeaths $10,000 to Mount Sinai Hospital and $5,000 to the Montefiore Home for Chronic Invalids.

Radium Institute of America.—At a recent meeting at the New York Yacht Club a society was formed for the study of radium, to discover any radiferous deposits in the United States and to buy quatities of the substance in Europe for clinical use in the United States. The idea of the founders of this society is to establish a clinic in connection with some hospital where radium treatment will be administered free to those who need it. They will endeavor to protect the public against the claims of patent-medicine manufacturers. The following officers were elected: President, Dr. Charles F. Chandler, professor of chemistry in Columbia University; vice-president, Dr. Robert Abbe; secretary, Prof. William Hallock, of the Department of Physics, Columbia University; assistant secretary, Prof. George B. Bertram of the same department; treasurer, Dr. Hugo Lieber, manufacturing chemist.

Tuberculosis Preventorium for Children.—The report of the first preventorium established in the United States emphasizes the fact that prevention of tuberculosis is easier and better than its cure, as overcrowding breeds disease, and quicker results from the relief of congestion are obtained by taking children of tuberculous patients into the country before the infection takes deeper root and the change is absolutely necessary. In this way it is noteworthy that within three months children may be fully restored to health. This work was influenced and made possible by Mr. Nathan Straus, who presented the Grover Cleveland Cottage and eight acres of pine land surrounding it, and the majority of stock in the Lakewood (N. J.) Hotel property, in which his investments amount to half a million dollars. Possession was taken of the cottage in May; the porch was arranged for six beds and the house for fourteen. The girls were all placed in this cottage, and in addition rooms for the matron and the help were provided and a dining room with accommodation for from forty to fifty children. Near the cottage has been built an open-air camp about 100 feet long to accommodate twenty boys. Since the opening of the institution, ninety-two boys and girls ranging from 4 to 14 years of age have been received. During their stay they have been in good health, showing steady improvement in general condition and gaining in weight. Plans are being made to increase the capacity of the institution to 400 children by next summer. The preventorium proposes not only to treat such children as need help but to carefully "follow up" such children and look after their welfare for some time after they have been discharged from the preventorium. A department of industrial education is to be arranged to include carpentering, cobbling, basketry, weaving, stencil work, medal work, etc. This department has been endowed by Miss Dorothy Whitney with $100,000, the interest of which will pay for instruction, tools, and materials. The medical service of the institution has been in charge of Dr. Alfred F. Hess, who has visited the institution at least once a week and has kept in touch with details. Drs. Abraham Jacobi, Hermann M. Biggs and Sigismund S. Goldwater has aided materially by their expert advice, in bringing about a practical organization.

New York City

Hospital for East New York.—Plans for the new Bradford Street Hospital in the East New York section of Brooklyn have been filed. The hospital will cover an entire block and will have a capacity of 100 beds. The estimated cost will be $350,000.

Lower Temperature in School Rooms.—Dr. C. Ward Crampton, director of physical training in public schools, has sent out a notice to all school teachers ordering them to keep the temperature of school rooms at 68 degrees instead of 70 as has been the practice. Dr. Crampton holds that the pupils will do better work if the air is cooler, and it is stated that there is likely to be a further general reduction of temperature in a short time. In England the school rooms are kept at a mean temperature of 60 degrees.

Neurological Institute Opened.—The New York Neurological Institute for the treatment of nervous and mental diseases, said to be the first of its kind in the United States, was opened this week at 149-151 East Sixty-seventh street. The building is six stories in height and fireproof. Dr. Joseph Collins is chief of staff of the medical board, and associated with him are Drs. Pearce Bailey and Joseph Fraenkel, assistant physicians; Dr. Smith Ely Jelliffe, alienist; Dr. Moritz Gross, in charge of the hydropathic department; Dr. Augustin A. Wolf, in charge of the electrotherapeutic department; Dr. D. M. Kaplan, in charge of the laboratory; and consulting physicians, Drs. Charles L. Dana, Francis P. Kinnicutt, Hermann M. Biggs, and Bernard Sachs, Dr. George G. Taylor is house physician. Much of the work done is on a charity basis, but patients may be taken at a cost of from $10 to $15 per week. The dispensary is to be open daily for charity cases only. The special province of the institute is the treatment of nervous and mental diseases with the minimum of medical and surgical interference.

OKLAHOMA

Physicians to Withdraw Advertisements.—Jefferson County Medical Society has asked all physicians belonging to the society to withdraw their advertisements from local newspapers.

Tuberculosis Exhibition.—Under the auspices of the State Medical Association and the State Board of Health, a convention on tuberculosis and exhibition will be held at Oklahoma City, January 10 and 11, at which ways and means will be discussed for the prevention and eradication of tuberculosis.

Personal.—Dr. John W. Riley has been selected as commissioner of health of Oklahoma City.——Dr. Benjamin F. Hamilton has been appointed physician in charge at the Government Indian School, Shawnee.——Dr. James H. Proffitt, Oklahoma City, was seriously injured in a collision between an interurban car and an automobile, September 3.

Cornerstone Laid.—The cornerstone of the new hall of the University of Oklahoma, Norman, was laid November 16, with Masonic ceremonies. The new building will relieve the crowded condition of the medical department of the university, to which it has been subjected since the destruction by fire last year of one of the largest buildings of the institution.

Licenses Revoked.—The license of Dr. J. M. Means, Claremore, charged with performing a criminal operation, is said to have been revoked, October 13, by the State Board of Medical Examiners. At the same session the license of Dr. Leander M. Overton, Guthrie, was revoked on the ground that he was a graduate of a medical college whose diploma was not recognized by the board. Dr. Overton has filed suit against the State Board, and has asked that it be enjoined from molesting him in the practice of medicine.

Antituberculosis League Organized.—The Oklahoma Colored Antituberculosis League was organized in Oklahoma City, November 18, at a meeting held in conference with Dr. John C. Mahr, Shawnee, state superintendent of health. A local organization in every negro church in the state is planned, and a vice-president is to be appointed to organize the colored people of each county in their campaign against tuberculosis. Dr. Horace W. Conrad, Guthrie, was elected president; W. E. Brooks, Shawnee, secretary; and Dr. Riley A. Ransom, Sewell, treasurer.

SOUTH CAROLINA

Student Magazine is Issued.—The first issue of the *Aesculapian*, a monthly journal issued by the students of the Medical College of the State of South Carolina, Charleston, appeared November 18.

State Board of Charities Needed.—At the state convention of charities and corrections, which met in Columbus, November 19, a resolution was adopted asking the legislature to establish a state board of charities.

Personal.—Drs. Edgar A. Hines, Seneca, and William Eggleston, Hartsville, have been appointed members of the executive committee of the State Board of Health, vice Dr. J. Adams Hayne, Greenville, and Dr. James Evans, Florence, deceased. ——Dr. J. Sumter Rhame, Charleston, has returned from abroad.——Dr. A. Robert Taft has been elected professor of materia medica in the Medical College of South Carolina, Charleston, vice Dr. John Forrest, resigned.

Society Meetings.—At the annual meeting of the Fourth District Medical Association, held in connection with that of the Pickens County Medical Association at Easley, November 15, Dr. William A. Tripp, Easley, was elected president; Dr. Curran B. Earle, Greenville, vice-president, and Dr. Ernest W. Carpenter, Greenville, secretary-treasurer.——At the annual meeting of Lexington County Medical Society, held in Lexington, October 4, Dr. Frank R. Geiger, New Brookland, was elected president; Dr. Rufus E. Mathias, Irmo, vice-president; and Dr. James J. Wingard, Lexington, secretary (reelected).

PENNSYLVANIA

Tuberculosis Mortality.—According to a report issued by the State Department of Health, November 24, the deaths from tuberculosis reached 10.211 in 1908, a decrease of 614 from the number reported in 1907. The report shows that the average age at death was 35.5 years. Sixty-six per cent. of all deaths from this cause occurred between the ages of 25 and 64.

Hospital Suit Dismissed.—On November 24, Judge Brommall, of Media, non-suited the damage cases of Joseph Gallagher and Charles Firth against the Chester Hospital, on the ground that a public charitable institution is not responsible for the negligence of its agents, servants or employees. Legal action, he said, could be taken against the parties responsible but not against the institution.

Tuberculosis Sanitarium for Teachers.—A private sanitarium for the treatment of tuberculosis is to be established at Mount St. Michaels' Seminary, Berks county. The institution is to be erected on a tract of 52 acres of land, 600 feet above sea level. The sanitarium will be devoted exclusively to the treatment of tuberculosis in sisters teaching in the Roman Catholic parochial schools of Pennsylvania.

Personal.—Dr. F. R. McGrew, of Carnegie, was recently seriously injured by a collision between his automobile and a railway train.——Dr. Orlando Logan, Girard, the oldest physician in the Erie County Medical Society, has been presented with a cane by the society.——Dr. Edward B. Mathiot, Pittsburg, was seriously injured in a runaway accident November 23.——Dr. W. H. Chambers has succeeded Dr. W. M. Downey, resigned as a member of the board of health of McKeesport. ——Dr. Benjamin Thompson, Landenburg, is ill with cerebral hemorrhage.——Dr. Frederick A. Rupp has resigned as a member of the Lewistown Board of Health.

Philadelphia

Build Nurses' Home.—Work is to be immediately started on a four-story building to be used as a nurses' home at the Philadelphia General Hospital to cost $13,000.

Personal.—A destructive fire occurred in the home of Dr. John K. Mitchell, November 22, the damage amounting to about $5,000.——Dr. Edw. E. Montgomery was the guest of honor at the regular meeting of the Buffalo Academy of Medicine, November 26.

Bequests.—The will of the late Rebecca Hay bequeathes $20,000 to the Presbyterian Orphanage and $10,000 to the Presbyterian Hospital for the support of free beds.——By the will of the late Anna J. Van Reed of Reading, the Medico-Chirurgical Hospital receives $13,000.

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, amounting to about $180, will be made on July 14, 1910, provided that an essay deemed worthy of the prize shall have been offered. Essays intended for competition may be on any subject in medicine, but cannot have been published. They must be typewritten, and must be received by the secretary of the college on or before May 1, 1910. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. The successful essay or a copy of it is to remain in possession of the college; other essays will be returned on application within three months after the award.

TENNESSEE

Health Day.—In accordance with the annual custom, November 19 was observed as public health day throughout the state. Literature was sent by the state superintendent of education to all schools, and addresses were made at the various schools by physicians on that day.

Personal.—Dr. Charles F. Forgey, Columbia, who has been a patient in St. Thomas Hospital, Nashville, has returned home. ——Dr. Arthur H. Gray, Nashville, has been made superintendent of the new hospital at Seattle, Wash.——Dr. James T. Jones, Jackson, has been elected president of the city board of health.

Medical College in Hands of Receiver.—The Tennessee Medical College, Knoxville, now known as the Medical Department of Lincoln Memorial University, is said to have been placed in the hands of a receiver, November 2, by the chancery court, following the filing of a bill by several creditors of the institution. Dr. Walter S. Nash, Knoxville, was named as receiver.

Knoxville Antituberculosis Society.—At a meeting of the board of directors of the Knoxville Association for the Prevention and Cure of Tuberculosis, November 1, it was decided to apply for a charter of incorporation so as to legalize the society and place it on a firmer foundation. Dr. William R. Cochrane, secretary of the city board of health, was elected a director, vice Dr. Chalmers Deadrick, resigned.

TEXAS

Quarantine Raised.—By proclamation of the governor, the quarantine against ports south of 25 degrees north latitude was raised November 1.

Medical Students Issue Paper.—The *Microbe*, a monthly publication issued by the students of the Medical Department of Fort Worth University, made its initial appearance November 1.

Personal.—Dr. Paul Renger, city physician of Hallettsville, has been appointed physician for Lavaca county.——Dr. Zachary T. Scott, Clifton, has succeeded Dr. Lewis B. Bibb, resigned, as registrar of vital statistics of the state——Dr. Cyrus B. Weller, Austin, has been appointed assistant city health officer.

Innovations Advocated.—Superintendent Nichols of the Southwestern Insane Hospital, San Antonio, in his annual report, recommends the building of an east wing on the infirmary to cost $6.000; the erection of a natatorium and bath house to cost $12,000, and the purchase of a sight-seeing motor car with seating capacity of twenty-five, for the use of patients.

Constitutionality of Medical Law to Be Tested.—The constitutionality of the one-board medical act, passed by the thirtieth legislature, is to be tested in the United States Supreme Court. Presiding Judge Davidson of the court of criminal appeals, on November 9, granted a writ of error to the United States Supreme Court in the case of Ira Collins, El Paso, who was fined for practicing osteopathy without having obtained a license from the board. The court held that osteopaths, although they do not use medicine in practice, come within the provisions of the act.

Elect Officers.—At the annual meeting of the Northeast Texas Medical Association, held in Marshall, November 16, Dr. Holman Taylor, Marshall, was elected president; Dr. Walter J. Matthews, Mount Pleasant, vice-president; Dr. Robert H. T. Mann, Texarkana, secretary; and Dr. Charles A. Smith, Texarkana, treasurer. The next meeting of the association will be held in Texarkana.——At the meeting of the Seventh District Medical Society in Austin recently, Dr. Washington A. Harper, Austin, was elected president, vice Dr. Matthew A. Taylor, Austin, deceased.——Wise County Medical Society, at its annual meeting, held in Decatur, November 18, elected Dr. John A. Embry, Decatur, president; Dr. Elden H. Foster, Bridgeport, vice-president; Dr. John F. Ford, Decatur, secretary; Dr. Ambrose C. Bramlett, Decatur, treasurer; Dr. B. M. Jones, Boyd, censor, and Dr. Leopold H. Reeves, Decatur, delegate to the state association.——The Lone Star State Medical, Dental and Pharmaceutical Association held its annual meeting in Houston, November 9-11, and elected the following officers: President, Dr. Napoleon J. Atkinson, Greenville; vice-president, Dr. Russell F. Ferrill, Houston; secretary, Dr. Richard T. Hamilton, Dallas; assistant secretary, N. F. Wallace, Fort Worth; and treasurer, Miss A. E. Hughes, Clarksville, and chairmen of sections, Dr. Benjamin R. Bluitt, Dallas, surgery; Dr. William T. Hughes, Fort Worth, practice of medicine; Dr. Felix A. Bryan, Dallas, gynecology; Dr. Rufus S. Childs, Houston, tuberculosis; Dr. Mary S. Moore, Galveston, obstetrics; Dr. William M. Drake, Marshall, pathology; Dr. Ransom B. Barnes, Cleburne, genitourinary diseases; Dr. Henry E. Lee, Beaumont, hygiene; H. M. Whitey, Houston, dentistry; and G. W. Lemons, Fort Worth, pharmacy. Austin was selected as next place of meeting.

VIRGINIA

Medical Faculty Meets.—At the annual meeting of the Petersburg Medical Faculty, November 19. the following officers were elected: President, Dr. Leverett S. Early; vice-presidents, Drs. W. Preston Hoy, and Hampden A. Burke; secretary-treasurer. Dr. William C. Powell; corresponding secretary, Dr. J. R. Beckwith, and court medical, Drs. Samuel A. Hinton, Franklin W. Hains, William H. Crockford, Jr., J. Bolling Jones, and Daniel D. Willcox.

Personal.—Dr. George K. Sims, Richmond, was operated on November 17. at the Memorial Hospital.——Dr. Truman A. Parker. Richmond, has been elected executive secretary of the Virginia Antituberculosis Society.——Dr. Charles R. Grandy, Norfolk, has been elected a vice-president of the Virginia State Antituberculosis Society, and Dr. Charles P. Wertenbaker. U. S. P. H. and M.-H. Service, Norfolk, a director.——Dr. John W. Winsten, Norfolk, has been appointed captain and assistant surgeon, N. G. Va.

State Antituberculosis Association Organized.—The Virginia Antituberculosis Association was organized at Richmond, November 6. Dr. William F. Drewry, Petersburg, was temporary chairman, and Dr. Albert W. Freeman, Richmond, temporary secretary. The following permanent officers were elected: President, Capt. W. W. Baker, Hallsboro; vice-presidents, Governor-elect William Hodges Mann, Governor Claude A. Swanson, President Edwin A. Alderman of the University of Virginia; Dr. Elliott T. Brady. Abingdon; Right Rev. Augustin Van de Vyver, Bishop of Richmond; Dr. Rawley W. Martin, Lynchburg; Dr. Stephen Harnsberger, Catlett; John S. Bryan, Richmond; and Dr. Charles R. Grandy, Norfolk; secretary, Miss Ann Gulley. Richmond; treasurer, Thomas W. Scott, Richmond; and directors, Dr. Charles P. Wertenbaker, U. S. P. H. and M.-H. Service, Norfolk; John T. Maginnis, Radford; Dr. William F. Drewry, Petersburg; George W. Wright, Marion; Mrs. John W. Hayes. Petersburg; Rev. J. T. Mastin, Richmond; Mrs. D. W. Reade, Charlotte; Dr. Ennion G. Williams, Richmond; Dr. Ernest C. Levy, Richmond, and Miss S. H. Cabiniss, Richmond.

WASHINGTON

Local Physicians Elect.—At a meeting of the North End (Seattle) Medical Society, October 29, the following officers were elected: Dr. Walter K. Seelye, president; Dr. Clarence W. Knuedson, vice-president; and Dr. J. Tate Mason, secretary-treasurer.

Hospital Contract Awarded.—The general contract for the erection of the buildings for the Vancouver Branch of the Sisters of Charity of the House of Providence has been awarded to contractors in Vancouver for $111,000. The building is to have a frontage of 160 feet, with a width of 48 feet, a central wing projecting 72 by 35 feet. The building will be practically fireproof.

Personal.—Dr. Elmer M. Brown, Tacoma, has been commissioned colonel and assistant surgeon in the National Guard of Washington, and Dr. John S. Kulp, major, medical corps, U. S. Army, retired, has been commissioned lieutenant colonel and chief surgeon of the medical corps.——Dr. C. R. Duncan is reported to be critically ill with typhoid fever at the home of his sister in Cle Elum.——Dr. Joseph L. Lane, physician at the state penitentiary, Walla Walla, has resigned and will begin practice in Seattle.

WEST VIRGINIA

Free Antitoxin.—The State Board of Health, at its meeting in Parkersburg, November 10, decided to place antitoxin for the treatment of diphtheria in every county in the state for the benefit of those unable to purchase it.

Antituberculosis League Organized.—The Antituberculosis League of Moundsville was organized November 15, with V. A. Weaver, chairman, and A. R. Bennett, secretary. It was arranged to hold an antituberculosis exhibit during December. Drs. LeRoy S. Hennen, John C. McCollough, and Joseph A. Striebach were appointed a committee of arrangements.

Medical Society Meeting.—The Grant-Hampshire-Hardy-Mineral Counties Medical Society held its annual meeting in Burlington, October 22, and elected the following officers: President, Drs. James W. Shull, Romney; vice-presidents, Drs. William T. Highberger, Maysville, Robert W. Love, Moorefield, George H. Thomas, Romney, and Hugh Strachan, Blaine; secretary, Dr. W. Holmes Yeakley, Keyser; treasurer, Dr. Walter M. Babb, Keyser, and censors, Drs. Glenn Mooman, Petersburg, George H. Thomas, Romney, R. W. Love, Moorefield, and Lloyd L. Edgell, Keyser.

WISCONSIN

Marinette County Physicians Meet.—The annual meeting of the Marinette County Medical Society was held in Marinette, November 9, when the following officers were reelected: President, Dr. H. F. Schroeder; vice-president, Dr. Simon Bergland; and secretary-treasurer, Dr. Sherman E. Wright, all of Marinette. Dr. A. F. Lyon Campbell, Dunbar, was elected censor.

Personal.—Dr. L. Rock Sleyster, Appleton, has been appointed physician to the state penitentiary, Waupun, vice Dr. Moore, who has been appointed superintendent of the State School for the Blind, Janesville.——Dr. Mazyck P. Ravenel, Madison, has been reelected president, Dr. Hoyt E. Dearholt, Milwaukee, executive secretary, and Dr. Clarence A. Baer, Milwaukee, secretary of the Wisconsin Antituberculosis Society.——Dr. L. Ward Alger, the oldest practitioner of LaCrosse, announces that he will retire from practice and move to Everett, Wash.

Officers of Hospital for Chronic Insane Elected.—At the annual meeting of the trustees of the Milwaukee County Asylum for Chronic Insane, Wauwatosa, Dr. William F.

Beutler was elected superintendent and medical officer for the fifteenth consecutive term, and the following members of the honorary medical and surgical staff were reelected: Drs. Gustav A. Kletzsch, Uranus O. B. Wingate, A. Hamilton Levings, Ernest C. Grosskopf, Louis Fuldner, Christian H. Beyer, Franklin H. Hagerman and Gustavus I. Hogue, Milwaukee, and Drs. Ferdinand M. Scholz, Moses J. White, Richard Dewey, and Edward A. Schmitz, Wauwatosa.

CANADA

Personal.—Dr. Oscar Klotz, for seven years assistant in pathology to Prof. John G. Adami at McGill University, Montreal, has been appointed professor of pathology in the University of Pittsburg and will enter on his new duties about the New Year.——Dr. H. H. McIntosh has resigned from the superintendency of the Vancouver General Hospital and Dr. W. A. Whitelaw succeeds him.——Drs. George A. Kennedy, McLeod, Alta.; Thomas J. Costello, Calgary, Alta.; and Robert G. McDonald, Sarnia, Ont., have gone abroad.——Dr. George H. Parke, Quebec, has been appointed surgeon to the garrison at St. Johns, P. Q., vice Dr. Chevalier, resigned.——Dr. Hugh A. McColl, Milton, Ont., has returned from Europe.

Dominion Registration.—Dr. Thomas G. Roddick called a meeting of the committee of the Canadian Medical Association on Dominion Registration in Montreal, November 16. British Columbia, Manitoba, Ontario, Quebec, New Brunswick, Nova Scotia and Prince Edward Island were represented and the following medical councils or provincial examining boards sent delegates to confer with this committee: Nova Scotia, New Brunswick, Quebec and Ontario. The meeting was called to consider the resolution practically unanimously passed at the annual meeting of the Canadian Medical Association held in Winnipeg in August, which provided that the Roddick Act be put in force whenever five or more provinces agreed to the provisions of the act. It is understood that the meeting was an entirely satisfactory one and that steps will be taken to have amendments made to the Canada Medical Act of 1902 at the present session of the federal parliament.

Tuberculosis.—The Royal Edward Institute for the care of patients suffering from tuberculosis in Belmont Park, Montreal, was opened by King Edward October 22. Addresses were made by Sir George Drummond, president of the institute; Sir Charles Fitzpatrick; Dr. R. W. Philip, Edinburgh, Scotland, and others.——The Lake Edward (Que.) Sanatorium for the care of patients suffering from tuberculosis was opened October 14. The institution has accommodation for about thirty patients and is intended only for incipient cases. Dr. William E. Ainley, Lachine, has been appointed medical superintendent.——The buildings of the Ninet's Sanatorium, Brandon, are nearly completed and will be ready for occupation about Christmas.——A tuberculosis commission from New Brunswick, consisting of Drs. John R. McIntosh and A. F. McAvenney, St. John, Dr. Robert L. Botsford, Moncton, and Dr. Bourk of Kent county, has recently been in Boston on a tour of investigation and study of the tuberculosis problem in that city.

Hospital News.—At the annual meeting of the Montreal Maternity Hospital held recently, Dr. Andrew MacPhail was made a life governor. Owing to the unsatisfactory financial condition of the hospital, an appeal will be made to the public for better and larger financial support.——The Alexandra Hospital for contagious diseases, Montreal, recently appealed to the public for funds to wipe out its mortgage indebtedness of $100,000, of which amount $30,000 was received. The work in connection with this hospital is increasing very rapidly. During the first ten months of 1908, 367 patients were admitted, while for the corresponding period of 1909, 561 have been received.——Regina, Sask., is erecting a new hospital at a cost of $100,000, to be finished by December, 1910.——Calgary, Alta., is erecting a new hospital in which fraternal societies will furnish wards, while several private individuals will furnish rooms.——The Provincial Royal Jubilee Hospital, Victoria, B. C., is erecting a new Maternity Home.——A new hospital for the insane is being erected at Coquitlam, B. C. It will be called Mount Helmcken, after Dr. J. S. Helmcken, Victoria, dean of the medical profession of British Columbia.

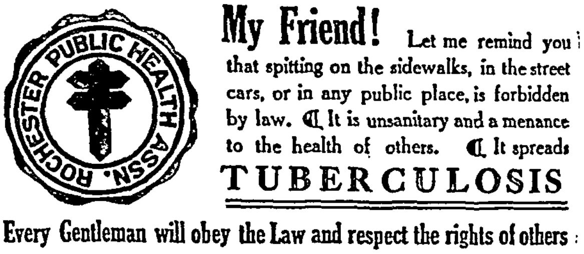
GENERAL NEWS AND COMMENT

Surgeons and Gynecologists to Meet.—The twenty-second annual session of the Southern Surgical and Gynecological Association will be held in Hot Springs, Va., December 14-16, under the presidency of Dr. Stuart McGuire, of Richmond, Va.

Interurban Officers.—Officers of the Interurban Academy of Medicine, whose membership includes physicians of Duluth, Minn., and Superior, Wis., were elected at the annual meeting held November 17, in Superior. Dr. Charles H. Mason, Superior, was elected president; Dr. Robert Graham, Duluth, vice-president; Dr. Thomas J. O'Leary, Superior, secretary-treasurer, and Dr. Edward L. Tuohy, Duluth, censor.

Mexican Medical Congress.—The fourth Mexican National Medical Congress is to be held in the City of Mexico, Sept. 19-25, 1910. The congress consists of physicians, druggists, veterinarians, dentists and sanitary engineers. The congress will award a prize of 1,000 pesos ($200) to the author of the address which may be declared the best, by a jury consisting of five individuals appointed by the president and vice-presidents of sections. The president of the congress is Dr. Porfirio Parra, and the secretary, Dr. Luis E. Ruiz, both of the City of Mexico.

To Discourage Spitting.—The Rochester (N. Y.) Public Health Association has printed quantities of a small yellow slip containing the accompanying statement, printed in red and black. These are for free distribution by policemen, street car men and others who are interested in the fight against promiscuous spitting. It is hoped to suggest to offenders the necessity of proper observance of sanitary laws. This organization, whose address is 32 South Washington street, requests information, from others who have tried this method, as to the results observed.



My Friend! Let me remind you that spitting on the sidewalks, in the street cars, or in any public place, is forbidden by law. ¶ It is unsanitary and a menance to the health of others. ¶ It spreads

TUBERCULOSIS

Every Gentleman will obey the Law and respect the rights of others.

Tri-State Societies Meet.—The Tri-State Medical Association of Mississippi, Arkansas and Tennessee held its twenty-sixth annual convention in Memphis, November 16-18, under the presidency of Dr. William H. Deaderick, Marianna, Ark. The following officers were elected: President, Dr. James S. Rawlins, Danceyville, Tenn.; vice-presidents, for Mississippi, Dr. William L. Howard, Greenville; for Arkansas, Dr. John L. Jones, Searcy, and for Tennessee, Dr. Nicholas S. Walker, Dyersburg; secretary, Dr. J. H. Eugene Rosamond, Memphis (reelected); and treasurer, Dr. James A. Vaughan, Memphis (reelected). The association will hold its 1910 meeting in Memphis.——The Tri-State Medical Association of Arkansas, Louisiana and Texas held its annual session in connection with that of the Northwest Texas Medical Society at Marshall, November 16 and 17. The following officers were elected: President, Dr. Robert H. T. Mann, Texarkana, Ark.; vice-presidents, for Louisiana, Dr. Mathias M. Collins, Hosston, and for Texas, Dr. John O. McReynolds, Dallas; secretary, Dr. Jacob M. Bodenheimer, Shreveport, La.; and councilors, Drs. Holman Taylor, Marshall, Texas; Joseph E. Knighton, Shreveport; and Frederick W. Youmans, Lewisville, Ark. Shreveport was selected as the next place of meeting.

American Scientists to Meet.—The sixty-first annual meeting of the American Association for the Advancement of Science, and the eighth of the convocation week meetings, will be held in Boston, December 27 to January 1, on the invitation of Harvard University and the Massachusetts Institute of Technology, under the presidency of Dr. David Starr Jordan, president of Leland Stanford, Jr., University, Cal. The following societies have indicated their intention of meeting in Boston during convocation week: American Society of Naturalists, American Mathematical Society, Association of American Geographers, Geological Society of America, Association of Economic Entomologists, American Nature-Study Society, Association of American Anatomists, American Chemical Society, American Society of Vertebrate Paleontologists, American Society of Zoologists, American Physical Society, American [illegible] on, American Physiological Society, [illegible] Association, Entomological Society of America, American Folk-Lore Society, American Federation of Teachers of the Mathematical and the Natural Sciences, American Society of Biological Chemists, Sullivant Moss Society, Botanical Society of America, Society of Americar [illegible] tion of Mathematical Teachers in N[illegible] ociation of Physics Teachers, Physics [illegible] D. C., American Phytopathological Society, American Alpine Club, and American Breeders' Association.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Nov. 11, 1909.

Quacks on Trial

In the last few weeks two suits against quacks in Germany have attracted general attention. The first suit was for fraud against a spiritualist who had swindled the complainant out of $24,000 (100,000 marks), and who was sentenced to several months' imprisonment.

Still greater interest will be felt in a prosecution of the so-called clay pastor (*Lehmpastor*) Felke. In the Rhine country, a preacher named Felke for some years treated patients with water, air, light and earth, particularly with clay for local baths and poultices. He claimed to diagnose all possible diseases at the first look by certain changes, especially discoloration, of the iris. The fineness of this diagnosis is so remarkable that the pastor, as he stated at the trial, could tell whether any one ate much butter on his bread, whether the grandfather of the patient had had the itch, whether one had eaten an egg, and much more of the same kind. Thousands, among them well-to-do people from the better circles of society, consulted him.

One day he overlooked an appendicitis in a young man of 18 and by improper treatment caused his death. On trial for manslaughter by criminal carelessness, the court at Cleve acquitted him; the state's attorney appealed and the highest court in Germany, the imperial court, reversed the verdict and ordered a new trial in the county court at Krefeld. The height of excitement was reached when an opportunity was given the pastor, at the motion of the defense, and naturally with the support of the unprejudiced medical experts, among which were the renowned Professor Garré of Bonn, to exercise his eye diagnosis on twenty patients of the Krefeld city hospital. Not a single diagnosis was correct. Serious diseases were not recognized and symptoms were diagnosed which were not present. Even the fact that one patient was blind in one eye escaped the pastor.

The court decided that Felke had made a false diagnosis in the case involved in the trial and by prescription of improper measures had caused the death of the patient. In regard to carelessness, the court said the eye diagnosis was not reliable. However, inasmuch as the apparent successes of the treatment established by Felke and the respect of his patients extending almost to idolatry had confirmed him in the belief that he had the capacity of diagnosing disease correctly, the court gave an acquittal!

The state's attorney will appeal and there is no doubt that the imperial court will again reverse the decision. The imperial court has repeatedly expressed the view that quacks are responsible for their mistakes and liable to punishment in the same way as physicians. This is most distinctly stated in an opinion given in 1900, saying: "It is clear that an experience which dispenses with all scientific tests and basis for the connection between treatment and results has only the value of a guess and must always reckon with the danger of error and of mistakes and their consequences and that for this only the judgment of ordinary human intelligence is necessary. Whoever disregards this neglects his own capacity for thought and whoever undertakes the medical treatment of patients without having obtained the necessary scientific education is acting with a disregard of the attention necessary for such an employment which it is his duty to give it, i. e., is acting carelessly. Whoever exercises the healing of disease as a trade must acquaint himself with the rules of this science and must follow them if he is to escape the accusation of criminal carelessness against the life and health of another. And if he does not do this he is responsible for his offenses and their consequences."

On this principle the quack pastor will probably be convicted at the next trial. It is even more certain that, in spite of this, fools will still persist in their foolishness and quacks still find their supporters.

The Cholera

The cholera cases in East Prussia have not yet entirely disappeared. From the middle of July to the end of October, 33 cases have occurred, with 12 deaths. The government has instituted stringent measures requiring inspection of corpses by physicians, warning against the use of river water, supervising marine and river traffics (as without doubt the invasion of cholera from Russia occurs by water), installing steam disinfection apparatus at all quarantine stations and at the two cholera hospitals, and enforcing medical examination and baths for emigrants and immigrants and disinfection of their linen and clothing. The Russian raftsmen are returned to the border in closed cars.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Nov. 11, 1909.

Adulteration of Foodstuffs

The report on the budget of the Department of Agriculture gives an extensive review of the functioning of the service for the repression of fraud. During the year 1908, there were 67,726 samples of foods and drinks seized, out of which 14.4 per cent. were regarded as suspicious. Except in the Department of the Seine and some places where there were special agents, the seizures were made without discrimination. Sometimes the seizures are made on suspicion, and more frequently at random by way of control. In 1907 almost 20 per cent. of the samples seized were reported to the courts. In 1908 this average was lowered to 14.4 per cent., then to 14.1 per cent. in the first semester of 1909. The improvement was much more important in the provinces, where the average of suspicious samples was lowered from 18.3 to 10.4 per cent., but in Paris the average has risen from 23.7 per cent. to 31.6 per cent. At the period when the service for the repression of fraud began to act, the most frequently adulterated products were oil, milk, vinegar and wine. One of the most extensive frauds of recent years has been practiced in regard to mineral waters, both in the concerns which supply the groceries and in many of the most fashionable restaurants in Paris. The seizures of mineral waters began only at the end of the year 1907. The first case dates from Dec. 17, 1907, when a restaurant put ordinary water on sale in bottles bearing the trade-mark of a well-known mineral spring. In the course of 1908, numerous frauds in mineral water were brought to light in various restaurants which sold ordinary Paris drinking-water under the names of various mineral waters. From seizures made at groceries the service for the repression of fraud ascertained that the trade-marks of certain mineral waters have been tampered with. A strict surveillance was then placed over the wholesale dealers and at two wholesale establishments complete outfits for the manufacture of a mineral water were found. From October 22 to December 21 45,888 bottles of fraudulent water were sent out from the factory. In another factory the agents of the service for the repression of frauds found workmen occupied in filling bottles with "mineral water" that they were drawing from iron casks. The amount of ordinary water consumed by this concern, as registered on the meter, was, in 1907, 331,219 gallons (1,254,000 liters), and in 1908, 447,436 gallons (1,694,000 liters). The culprit confessed that he had made with ordinary water and bicarbonate of soda over 650,000 bottles of counterfeit mineral water.

Comparative Sanitary Conditions of the Troops at Paris and at Berlin

Last June, Dr. Lowenthal read before the *Académie de médecine* a paper on the comparative sanitary condition of the French and German armies from 1902 to 1906, from which it appeared that the general mortality in the French army was much larger than in the German army (THE JOURNAL, July 10, 1909, liii, 126). On November 9, Lowenthal placed the conclusion of his work before the academy, showing the mortality and morbidity of the garrisons of Paris and Berlin. This comparison is still more unfavorable. The general mortality of the army of Berlin is 10.5 per cent. lower than that of Paris. The morbidity from scarlatina in the army at Berlin is 25 per cent. lower and the mortality is 150 per cent. lower than that at Paris. In five years the number of measles patients in the Paris garrison is twice as numerous as in the whole German army; the number of deaths is seven times as large. The troops at Paris, if as numerous as the troops at Berlin (the garrison of Paris is composed of only 45,000 men against 65,700 men at Berlin) would furnish as many deaths from typhoid fever as the whole German army. The sanitary condition of the forces at Paris is deplorable not only as compared to that of the forces at Berlin, but even when compared with that of the army of the interior. Out of twenty corps of which the army of the interior is composed, the troops at Paris occupy the eighteenth place in the ascending scale of mortality and morbidity. The insalubrity of Paris, which increases each year because of the continual upheavals of the soil, is the primary cause of the unsatisfactory health of the troops, but another cause is the deplorable condition of the barracks, of which the greater number in Paris date from the 16th and 17th centuries, and meet the demands of modern hygiene hardly better than the cannons and guns of those periods satisfy the demands of modern warfare.

Mutual Benefit Societies and Social Hygiene

The *Alliance d'hygiène sociale* has taken advantage of the congress of the *Fédération nationale de la mutualité* which is now in session at Paris to draw the attention of the mutual benefit societies to the part which, even in their own interests, they ought to take in promoting social hygiene. M. Léon Bourgeois, former cabinet minister and president of the alliance, undertook to show the members that such societies would be acting wisely in their own interests if they employed part of their reserve funds (at present amounting to about 150,000,000 francs or $30,000,000) in the preservation of public health. In aiding the construction of cheap dwellings, for example, the mutual benefit societies would make a particularly advantageous investment, for they would then hinder one of the principal causes of long illnesses, particularly tuberculosis, the victims of which are such a heavy burden on the treasuries of the benefit societies. It was unanimously decided to form a permanent social hygiene commission of the mutual benefit societies, which will try to obtain from legislators and public authorities the right to use part of the reserve funds of the mutual aid societies in works of social hygiene, as has been done in Germany, where the insurance societies participate with so much success in the strife against tuberculosis. A particularly urgent feature is organization of insurance for chronic partial invalids, who, for lack of continued care, end by becoming permanent charges on the mutual benefit societies or on the public charities (*Assistance Publique*). The combat against unhealthful dwellings should also have an important place in the activities of the benefit societies, the improvement of the dwellings resulting in the decrease of the mortality from tuberculosis. If this double task cannot be accomplished by local societies, it is not beyond the powers of the department federations.

Election of Dr. Wurtz to the Académie de médecine

In its session of November 9, the *Académie de médecine* elected Dr. Wurtz an honorary member in the Section of Hygiene, Legal Medicine and Sanitary Police in place of Dr. Motet, who died last March. Dr. Wurtz, son of a celebrated chemist, is about 50 years old. He was a pupil of the late Professor Strauss, and when very young became successively professor *agrégé* at the Paris medical school and physician of the hospitals. He is known especially for his works on colonial pathology which he studied in the colonies, especially in Africa. One of the last missions that he accomplished was in Abyssinia, where for two years he was called on to attend the Emperor Menelik and his suite.

An Apostle of Repopulation

A few days ago Senator Piot died in his eighty-first year. He was one of those who first raised the cry of alarm in regard to the slow progressive depopulation of France. From his entry to the senate in 1897, M. Piot cooperated with the efforts of the statistician, Dr. Bertillon, against the decrease of the birth-rate in our country compared with the increase in other nations. He wrote many pamphlets and published two books, "Enquiry Into the Depopulation of France" (1899) and "Depopulation" (1903). All the acts of his political life were toward a single end, an effort against depopulation. To this end he proposed a bill for a special tax on bachelors and childless citizens; he obtained the creation of an extraparliamentary commission for the study of depopulation, the work of which unfortunately was interrupted by the lack of provision for its expenses. M. Piot also carried on an energetic campaign in favor of large families, which made him one of the most prominent political characters and won him the title of the "apostle of repopulation."

First Congress of Public Health Officers

A few days ago the first congress of sanitary physicians was held at the Pasteur Institute. It was due to the initiative of the Society of Public Medicine and Sanitary Engineering and was composed of public physicians and officers charged with the administration of the law of 1902 in regard to the protection of public health. Two of the questions discussed were of particular importance, namely, that of the reporting of infectious diseases, and that of the rôle of the departmental hygienic inspection. The congress resolved that the reporting of infectious diseases should be obligatory jointly on the head of the family and on the physician; also that the reporting of measles should be compulsory, disinfection being optional, and done at the demand of the family or of the physician. Dr. J. Courmont, professor of hygiene at the Lyons medical school, argued that the optional departmental service of hygienic instruction ought to be made compulsory for each department. The inspector ought to be a doctor of medicine and selected by competitive examination. His function should be to direct the service of disinfection and vaccination, to keep the sanitary records of the communes, to inspect unhealthful occupations, etc. The congress approved these conclusions. At the close of the congress a special commission met immediately to study the best means to bring about the necessary close relations between public physicians, sanitary officers and practicing physicians. The following are the conclusions of this commission:

1. It is important to improve the relations between practicing physicians and sanitary officers. The latter ought to furnish free when practicing physicians request it, everything necessary for isolation and disinfection.
2. Practitioners should have at their service laboratories where they can obtain free for their poor patients bacteriologic diagnoses in suspect cases. As moreover there are paying cases in which a practitioner may need bacteriologic diagnoses, but does not desire to inform the family, and as the service rendered is a public one, in such cases bacteriologic diagnoses should be furnished free to the practitioner.
3. Sanitary officials should try to reach an understanding with the physician of a case and to cooperate with him.
4. The practitioner in charge of the case should be invited to communicate his diagnosis as soon as possible and to point out suspected cases which are sometimes the most interesting from point of view of prophylaxis.

Congress of Sanitation and Salubrity of Dwellings

The third national congress of sanitation and salubrity of dwellings which has just been held at Paris, of which I mentioned the program in a previous letter (The Journal, Oct. 16, 1909, liii, 1304) also took up modifications to be made in the law of 1902 in regard to public health. It especially asked resolutions to the effect that the declaration for the disinfection of buildings in cases of contagious diseases ought to fall on the head of the family; it also resolved that a bill be brought forward authorizing expropriation on account of insalubrity, the expenses of expropriation to fall on the expropriated owner.

Prosecution for Delayed Report of a Case of Typhoid Fever

Dr. Forquin, a physician in Mirecourt (Vosges) was recently condemned to a fine of $10 (50 francs) for infringing the law in regard to the reporting of epidemic diseases. He had been called on April 5 to see a patient whose case he reported on April 27 as typhoid fever. He was prosecuted for his delay. He pleaded that his diagnosis had not been certain until the night of the 26th, and that consequently he was not able to make a report earlier. The court of Nancy, to which appeal was taken, reversed the decision of the lower court and acquitted Dr. Forquin.

The Ultra-Microscope and the Cinematograph

Much interest has recently been shown in a communication by Dr. Comandon to the *Académie des Sciences* in regard to the application of the cinematograph to the dark field microscope. According to Dr. Doyen cinematographic images of microscopic objects were made in London in 1906 by a distinguished naturalist, Mr. Marc Duncan.

International Conference Against Saccharin

On November 15, the international conference for the repression of the use of saccharin opened in Paris. Professor Bordas was elected president. The governments represented were those of France, Germany, Austria, Belgium, Greece, Hungary, Italy, The Netherlands, Portugal, Russia and Switzerland. The first session was devoted primarily to the examination of existing legislation for the repression of the sale and use of saccharin and similar sweetening substances.

Courses on Care of Infants

Dr. Maygrier, head accoucheur at the Maternité, has just inaugurated at the Fondation Pierre Budin (The Journal, June 19, 1909, lii, 2006) courses in "puericulture" from the earliest ages. This course will be completed in ten lessons and there will be several series during the school year.

Death of Professor Mayet

Dr. Octave Félix Mayet, former professor of general pathology at Lyons medical school, former physician of the hospitals of the same city, has just died, aged 74. He was the author of a treatise on medical diagnosis and semeiology in two volumes, published in 1897.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Nov. 20, 1909.

Short Sight in the Upper Classes

In delivering his presidential address to the Illuminating Engineering Society, Prof. Sylvanus Thompson, the eminent physicist declared that there was a greater percentage of short sight among the upper classes than among the poor. His explanation is that the illumination of the schools and colleges in which the children of the former class study, is defective and thus that in using their eyes the children are actually forced into short-sightedness. He reviewed the science of illumination from the days of rush-lights and candles to the present era of electric light and incandescent mantles, and he made a strong plea for an international unit of light. The present unit of so many candle power is vague and indefinite. It is now possible by the photometer to define the measurement of light. Why, therefore, should it not be employed for the measurement of light? There was no reason why schools and other public buildings should not be properly illuminated on a scientific basis. The factory acts contained no regulation except that the building should be "adequately lighted." What did adequate lighting mean? The health authorities had not a single photometer to ascertain whether buildings were adequately lighted or not. The only country in Europe which had sensible regulations on the point was the little kingdom of Holland.

Disease and Crime

The doctrine of the late Professor Lombroso that crime is due to an abnormal physical constitution of the criminal has not obtained much support in this country. The following extracts from the prison commissioners' report for England and Wales, 1909, shows, however, that mental and physical disease bear some relation to crime: "The number of convicted prisoners certified insane during the previous year was 97 men and 38 women, most of whom showed signs of insanity when admitted. There were 259 others listed as feeble-minded. At least 3 per cent. of the inmates of prisons are obviously mentally defective." In 1898 careful observations made of all youths detained in Pentonville (a large London prison) between the ages of 16 and 21 showed a deficiency of both height and weight. Their average height was two inches less than that of the general population and their weight average was fourteen pounds less. No fewer than 26 per cent. of them were afflicted with some disease, deformity, or disablement.

The Queen Alexandra Sanatorium at Davos

A new sanatorium for consumptives has been built under the patronage of the queen at Davos, the well-known Swiss resort for sufferers from that disease. It is to accommodate British patients who cannot pay for the charges of a private sanatorium. As the wooden structures used for sanatoria in England would not be suited for the climate of Switzerland, in which it is necessary to build in solid masonry, alike for durability and safe and efficient heating, the new sanatorium has been built of stone with concrete floors, roof, staircases, and balconies. The walls of the foundations, cellars, and basements are of immense thickness and the main walls are nowhere less than two feet. The building is close to Davotz Platz on the mountain side, about 300 feet above the town of Davos. The pine forest stretches almost to the doors, and affords a variety of sheltered walks. At present 54 patients can be accommodated, but the public rooms, kitchens, etc., have been constructed for the requirements of 120 and the building can be enlarged to furnish additional bedrooms. A new feature of the construction is that each patient will have a separate room divided from the others by a stone wall. As is always necessary in the high Alps, the outside doors and windows are double, but ample ventilation has been provided. The lodgment of dust is guarded against by the rounding off of all corners and angles. The resident staff consists of a medical superintendent, a junior medical officer, a matron, and two trained nurses, all of whom are British.

Compulsory Operations and Workmen's Compensation

As shown in previous letters the Workmen's Compensation Act, which renders employers liable for every accident which may befall a workman in the course of his employment, has caused considerable litigation. One point raised was whether a workman suffering from some disability is entitled to continue to receive a pension if the disability can be removed by an operation to which he refuses to submit. The point was first raised in 1903, when the court decided that no workman could be compelled to undergo an operation. In 1908 the point was again raised in another case when the court decided that the workman ought to have submitted to the operation and that his incapacity arose, not from the original injury, but from his unreasonable refusal to undergo operation involving only a slight risk. About the same time a similar case came before the Court of Appeal in Scotland, in which country the laws differ in many respects from those of England. In this case three out of five physicians recommended the amputation of a workman's second finger, which was crooked as the result of injury and interfered with his work. The court decided that his refusal to undergo operation destroyed his right to any further compensation, because like any reasonable person who wished to be restored to health, he should submit to an operation attended with little risk. A decision in a somewhat similar case has now been given by the English court of appeal in favor of the workman. This man was engaged on board a ship where he met with a serious accident which caused a double rupture. As he was suffering from disease of the kidneys his family physician advised him not to undergo an operation, though this was recommended in hospital. The judge in giving judgment said that the case was most important. The question was whether the man unreasonably declined operation. He could not admit that the man acted unreasonably under the circumstances in following his physician's advice. The judge in the lower court had decided to the contrary on the balance of the medical evidence before him as to whether the operation was reasonably safe or not. But that was not the real question; the point was whether the man had acted unreasonably in refusing to undergo the operation. After the evidence of his own physician his lordship thought that no amount of other medical evidence was relevant. He therefore allowed the appeal. The importance of this judgment is great, for it lays down the principle on which must be decided in future as to what is "unreasonable refusal" to undergo an operation.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Nov. 15, 1909.

Proposed Tax on Alcohol and Mineral Waters

The increased demand for funds for defensive purposes has prompted the minister of finance to suggest, among other taxes, taxes on medicinal waters and alcohol, which would materially hamper the treatment of disease. The tax on alcohol used in the composition of drugs, formerly only about 8 cents per liter or 4 cents per pint is expected to be not less than 20 cents. Pharmacists are already trying to produce remedies free from alcohol. The substitution of glycerin for alcohol has been shown to be possible in a good many prescriptions, so that the result of the increased tax would hardly meet the expectations of the government. Even more marked is public dissatisfaction with the proposed tax on mineral waters. In many places the ordinary water is not always quite reliable; therefore the natural sparkling waters are consumed in this country in enormous quantities; and medicinal waters are an absolute necessity with many persons. The tax would be a heavy burden as, although only 1 or 2 cents are to be levied per bottle, this runs up into high figures when the annual consumption is considered. Therefore, not only medical men, but also the *Curorte*—the health resorts which bottle such waters— have remonstrated. Not only the waters mentioned but all aerated waters, including the common "soda-water" are to be taxed. In one of the numerous mass-meetings to protest against such taxes, one of the speakers, a medical man, hit the nail on the head, saying that it was a wrong policy, if the state wanted to become stronger, to prevent the sick from regaining their health. This tax, together with the constantly rising prices for cereals and meat, is sure to bring down the national health from the comparatively high level it had reached a short time ago. Already some classes of the population have to reduce their annual consumption of meat, as the prices are getting exorbitantly high; on the other side, butter, fat and bread are also much dearer so that in the memorandum addressed to the government, medical bodies have pointed out these points too, which speak against the above-mentioned taxes being made lawful.

Medical Inspection of School Children

In a large number of cities an attempt has been made to ascertain through the public health officers the percentage of healthy and unhealthy children frequenting the public schools within a certain time; the results and conclusions are interesting. Altogether, about 250,000 children have been examined in the months of May, July, October and November (the end and commencement of our school year). Eyes, ears, nose, throat, teeth, condition of joints and bones as well as general health are chiefly examined; the ages of the children were from 6 to 14 years. Only 22 per cent. had normal teeth; those between the ages of 6 and 9, 13 and 14 were especially affected. The eyes were found myopic in only 10.5 per cent., hypermetropic in 3 per cent.; the percentage of both abnormal conditions was fairly constant at all ages, which is rather unexpected as regards the younger children at least. Tonsils were enlarged in 30 per cent., adenoids were present in 20 per cent.; both conditions in about 19 per cent. It could not be ascertained exactly in how many cases removal had been effected previously to examination. A fairly large percentage had chronic rhinitis, without adenoids. In 27 per cent. the nose was not normal, and deviations of the septum seemed to become more frequent in the older children. Affections of the ear were noted in 32 per cent.; mostly a simple catarrh of the tube and the tympanic cavity, while otorrhea was present in about 30 per cent. of the ear patients, that is to say, in about 11 per cent. of all children. Measles, scarlet fever and diphtheria were most often the cause. After-effects of rickets were noted in 20 per cent.; in another 5 per cent. the history allowed the assumption of the disease having been present. Disease of the joints was seen only in 3.5 per cent., mostly in the knee, then in the talocrural joint, then in the fingers (spina ventosa), then in the hip. Only 20 per cent. of all children could be classified as perfectly healthy; in the majority there were combinations of ear and nose and throat, or teeth and throat diseases. Disturbances in the function of the eye and ear were observed in 5 per cent.; of more than two important organs in only 2 per cent. Altogether the national physique would be supposed to be at a very low standard were it not proved that the majority of children outgrow their diseases, except the irreparable conditions of eye, ear and joints.

Pharmacology

THE UNITED STATES PHARMACOPEIA

The Report of the Committee of the American Pharmaceutical Association

It is important that physicians and pharmacists should become acquainted with the views of members of both of these professions in regard to the revision of the Pharmacopeia. We therefore review this committee's report (published in the *Am. Pharm. Assn. Bull.*, November, 1908, iv, 395), as one of the most important contributions from the pharmaceutical side. In regard to the scope and policy of the Pharmacopeia we quote the words of the report:

"The real and immediate interests of physicians and retail druggists should not be overshadowed by those of the large manufacturers, importers, food-officials and others, who desire the Pharmacopeia to be almost a universal standard for chemicals. It is to the best interests of the members of this association that the U. S. P. continue to be what its founders intended it, viz., a medium of communication between the prescribing physician and the dispensing pharmacist. It should not be made a standard for drugs which the retail pharmacist is not called on to dispense except in so far as the quality of the preparations which he does dispense is directly dependent on the quality of the crude drugs. It should not be a standard for articles, the chief uses of which are those of foods, beverages, or flavoring agents. . . . It is to the interest of this association that the Pharmacopeia be made to meet as nearly as possible the present-day needs of the medical profession. Hence we believe that full cognizance should be taken of the fact that the science of medicine is international and that every effort should be made to make the U. S. P. correspond as closely as practicable in strength of preparations, nomenclature, etc., to international usage."

If the views just quoted are followed there can be no possible ground of conflict between the medical and pharmaceutical professions over the revision of the Pharmacopeia. Physicians will probably feel disposed (and with good reason) to leave the question of botanical names to the discretion of others; also to a certain extent, chemical names except in so far as physicians demand that those which are to be generally employed shall be the least cumbersome that are consistent with scientific terminology.

A troublesome question is that of names of mixtures. It is evident that potent drugs should not be dispensed under names which favor forgetting their character. The committee states that only the hypercritical will object to the name of "compound mixture of glycyrrhiza," though that mixture contains a small amount of opium. The name sets a bad example at least; if there is enough opium in the mixture to produce its effect it should be indicated in the name; if the amount is too small to produce any effect it should be omitted from the preparation.

While the question of additions and dismissals from the Pharmacopeia rests primarily on the judgment of physicians, pharmacists are in a position to form an estimate of the attitude of the medical profession as a whole toward specific drugs; hence the committee presents lists of articles to be dismissed or added, and promises more complete lists at a later date. Pharmacists can also aid in determining which of certain commercial varieties of drugs are obtainable and which are not.

The committee takes up the question of increasing the number of assays of organic drugs; Lyons advises against this. It must be apparent to every physician that the time has come when we must introduce physiologic standardization for at least a few drugs, such as ergot, digitalis and strophanthus and their preparations, which are unsuited for chemical assay. Some pharmacists will urge the objection to this that only the larger manufacturing firms are in a position to standardize drugs physiologically and that this measure would compel the pharmacist to depend on these manufacturers. This argument should not be permitted to stand in the way of real progress.

A suggestion which will probably meet much favor at the hands of physicians, who should really have the larger share in deciding the point, is that all tinctures shall be made of uniform percentage strength.

If physicians will manifest as much interest in the forthcoming revision as the pharmacists are doing, and if the various problems concerned in revision be considered broadly, we should have a Pharmacopeia in which pharmacists and physicians may feel a just pride—a work which will command confidence and general respect and which will come to be regarded by all really progressive physicians as the storehouse from which to select agents for their prescriptions. Then shall we see the beginning of the end of the reign of the nostrum evil and the rise of legitimate pharmacy and therapeutics. It remains to be seen how far the selfish interests of certain manufacturers will be permitted to thwart this much-to-be-desired result.

Correspondence

Industrial Section of Congress on Hygiene

To the Editor:—Section IV of the International Congress on Hygiene and Demography, meeting in Washington, Oct. 1, 1910, will deal with industrial and occupational hygiene. This is an almost entirely unexplored field in our country and the coming congress offers for the first time an opportunity for a full discussion of the diseases incident to industry in the United States and the measures of prevention which should be advocated. Many papers dealing with conditions in Europe and England have been promised, and it is hoped that conditions in this country will also be thoroughly discussed. Physicians whose private or hospital practice lies among people of the wage-earning class are reminded that very little original work has been done by Americans in industrial diseases and that statistical studies of the morbidity rate in the different trades would be of great value. Communications regarding such papers should be sent to 1819 Q street, Washington, D. C.

George M. Kober, *President.*
Alice Hamilton, *Secretary.*

Dr. Jacobi Refuses to Endorse Promoter of Unethical Advertising

To the Editor:—I request you to publish this protest of mine against an attempt on the part of William Edward Fitch, M.D., the new editor of *Pediatrics* to use my name as that of a renegade from decent professional behavior. In the first number controlled by him, he places, without my permission or consent, my name at the head of his "Editorial Council," whatever that may mean. His introductory chapter on "Advertising in *Pediatrics*" sneers at those who look on "all advertising as venal muck" that would soil their "pharisaical fingers," and whom he calls "pharisaical pariahs," etc., and invites the "liberal patronage of legitimate advertisers." The editor might have known that I approve of purity and ethics in the medical profession, as represented in such of its magazines as are not mercenary or meretricious, and of its aversion to the advertising of nostrums. I shall thank you for publishing the following copy of a letter I sent to Dr. Fitch, November 19:

> I never read your first number until my attention was called to it by a western correspondent. In using my name as a member of your "Editorial Council" you made a mistake and committed a wrong. I never gave you permission; you never asked for it. In shaping your policy, I am sure you never consulted anybody who cares for the editorial standing and progress of the profession. That policy of yours may be successful from a financial point of view, which I doubt, however; for what you gain in advertisers, you will lose in readers and friends. It is an abomination. Please remove my name from the place it now occupies and have the goodness to tell your readers of your mistake. Yours truly,
>
> A. Jacobi.

November 22, I received the following reply:

> *Dr. Abraham Jacobi, New York City.*
>
> *Dear Doctor:* In reference to our telephone conversation of a few moments ago as stated, I now advise that I interpreted your letter in reply to my letter of September 15, to mean that you were willing to become a collaborator to the new *Pediatrics*. It seems that I have misunderstood the purport of your letter for which I am exceedingly sorry, since you would be the last gentleman in the world that we would care to offend, and we beg to assure you, dear doctor, that no offense, discourtesy, or anything of the kind was intended, and it will be our pleasure in our next issue (December) to make the necessary explanation and remove your name from the place it now occupies.
>
> Regretting the occurrence and imploring your forgiveness the writer begs to remain,
>
> Most sincerely and respectfully yours,
> W. E. Fitch, M.D.,
> Editor of *Pediatrics*.,

I am sorry to say that the courteous tone of this letter does not improve Dr. Fitch's position as a promoter of unethical advertising, nor that of his magazine as a worthy part of medical literature.
A. Jacobi, New York.

Comment:—In the October issue of *Pediatrics* (the first under the new management) it is stated editorially that:

> "No advertisements will appear in the advertising section of *Pediatrics* exploiting any pharmaceutical product, the manufacturers or proprietors of which do not freely and accurately give the exact character and ingredients entering into or forming its component parts."

In the same issue is to be found an advertisement of "enteronol," the nostrum which was exposed in The Journal Nov. 20, 1909. The Enteronol Company, it will be remembered, claims that it does not pay cash for advertising space but takes it "in trade"—either in "our guaranteed 7 per cent. preferred stock" or in enteronol itself. As to how accurately the "exact character and ingredients entering into" enteronol, are given by its manufacturers see the exposure in The Journal. Another editorial statement regarding the advertising standards of *Pediatrics* is:

> "Any advertisement containing dangerous or toxic ingredients will be refused."

This probably means that *products* "containing dangerous or toxic ingredients," etc., will not be advertised. Danger and toxicity are relative terms, but if used absolutely, then it would seem that *Pediatrics* will refuse to advertise most of the valuable drugs in the pharmacopeia; if used relatively then it would seem in order for that publication to drop the advertisement of what Mr. Adams calls "that hoary and dangerous fake. antikamnia," which is sent to the laity direct and which contains a heart depressant both dangerous and toxic.

> "Advertisements presenting extravagant or impossible statements will be refused."

On advertising page xv of the same issue of *Pediatrics* which contains the above excellent sentiments, occurs this statement:

> "Enteronol, the Greatest Gastro-Enteric Antiseptic and Germicide known to Medical Science."

If this is the editor's idea of a non-extravagant and not-impossible statement then his "rules and regulations to which all advertising must conform" will not offer insuperable barriers to the acceptance of peruna, Duffy's malt whisky or any "patent medicine" frauds.

The editor of *Pediatrics* says: "We hold that the advertising pages of every scientific publication is [are?] entitled to a 'square deal.'" It is respectfully suggested that the medical profession and the public are also entitled to a "square deal," and when the frauds and humbugs of the proprietary world are exploited in the pages of a medical publication the medical profession and the public are not getting it.

We do not blame Dr. Jacobi for his evident indignation. It would be interesting to know how many more physicians' names have been thus misused.

Miscellany

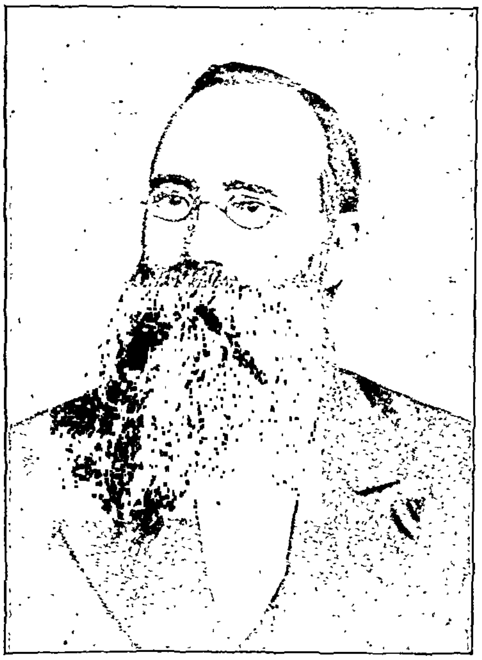
The Quack and the Laity.—Maynard A. Austin (*Indianapolis Medical Journal*, October, 1909) holds that the practitioner of medicine alone is to blame for any lack of standing he may have in his community. This neglect of psychologic principles, he believes, has been the cause of the great success of the religio-medical movements. Considering the personality of the average quack, he must be credited with exhibiting a good front on all occasions and always making occasions for putting up the front. He is egotistic and in his egotism believes himself capable of much that is beyond his ability. Patients are impressed with this sort of thing, and against their own judgment will place themselves in the hands of such men. An interesting fact is the ease with which fees are secured by quacks in advance, while the home doctor waits six months to five years, and feels lucky if he gets his pay then. If a patient pays out a hundred dollars to be cured of some malady, that hundred dollars is going to be a wonderful inducement for that patient to carry out every instruction that is given to him. If he sees his family doctor once a week, and pays him a dollar or two (or has it charged on the books) the patient is little or nothing out. and with the average patient with a chronic affection, the amount of assistance he gives in helping himself get well is a negligible quantity. To do away with all these things Austin regards as an impossibility. So long as people live and suffer, the reputable physician will have to contend with impostors and charlatans. To do away with the worst features of quackery is a matter of education, not condemnation. Few physicians, to say nothing of the laity, know of the various schemes the "patent-medicine" concerns are working to gain the confidence of, and much valuable information from, the women of various cities. Under the pretext of giving health lectures, hygienic demonstrations and physical culture training, a number of women are employed who go out in the various cities with letters of introduction and a good front, approach a few of the prominent club women and get in touch with the church people through the ministers and ministers' wives. One of the peculiar facts of the business is the ease with which the churches are secured for the furtherance of these affairs, and occasionally it has leaked out that the minister has been the recipient of a percentage. This is not to be wondered at in the light that the religious papers have been among the worst offenders in the class of advertising they carried. One church paper, recently inspected by Austin, carried thirteen advertisements offering cures for such conditions as cancer, consumption, fits, rheumatism and other chronic conditions for which no certain cure has ever been discovered. These conditions are brought about not only by the superstition of the laity, but also by their refusal to believe—when told them by their physicians—that some conditions have no certain cure, that others are incurable and that others need nothing but mental treatment because they are purely imaginary. Austin says that even the reputable profession could be given a house-cleaning with great benefit, moral, professional and financial, to the good of the profession itself and the physical and financial welfare of the laity.

Deaths

William Biddle Atkinson, M.D., a member of the American Medical Association since 1859 and its permanent secretary from 1864 to 1899; died at his home in Philadelphia, November 23, aged 77. He was born in Delaware county, Pa., received his preliminary education in Philadelphia, and commenced the study of medicine in 1850 under the preceptorship of Dr. Samuel McClellan, one of the founders of Jefferson Medical College and the Pennsylvania Medical College, Philadelphia; after a three-years' term of study he was graduated from the Jefferson Medical College in 1853. For several years thereafter, in addition to the practice of medicine, he taught mathematics and the classics at Gregory's Classical School.

In 1854 he became a member of the Philadelphia County Society; was its secretary for seven years; a reporter of its proceedings for medical journals, vice-president of the society, and in 1873 its president. He was permanent secretary of the Medical Society of the State of Pennsylvania from 1862 to 1897; secretary and later president of the Northern Medical Association of Philadelphia, and in 1894 was elected president of the State Associated Health Authorities of Pennsylvania.

For several years Dr. Atkinson acted as correspondent of the *New Jersey Medical and Surgical Reporter*, *New York Medical Times*, *Nashville Medical Journal*, *New Orleans Medical Journal* and others; in 1858 he became associate editor of the *New York Medical and Surgical Reporter*, and a year later was appointed editor of the department of obstetrics and diseases of women and children in the *North American Medico-Chirurgical Review*. His literary work also included the editing of the annual volume of transactions of the American Medical Association; the publication of several annual editions of the Philadelphia Medical Directory, a biography of physicians and surgeons of the United States, and many valuable monographs on obstetrics and gynecology.



William Biddle Atkinson, M.D.

He commenced his medical teaching as assistant professor of obstetrics and diseases of women and children in the Pennsylvania Medical College in 1859, retaining this position for two years until the college became defunct, and at this time he conducted the only gynecological clinic in the city; from 1877 to 1886, he was lecturer on diseases of children in Jefferson Medical College, and in 1887 was made professor of sanitary science and pediatrics in the Medico-Chirurgical College.

During the Civil War he served as acting assistant surgeon in the army for two years, and from the creation of the State Board of Health in Pennsylvania in 1886, was medical inspector. In 1861 he was made physician to the department of diseases of children, and president of the staff of Howard Hospital, Philadelphia, and held this position for several years. The American Medical Association owes much to Dr. Atkinson, who, during the years of relative weakness of the organization, served faithfully as its secretary, sparing neither time nor strength for the furtherance of its best interests and its upbuilding.

Frank Bradford Sprague, M.D. University of Vermont, Burlington, 1889; a member of the American Medical Association, New York Academy of Medicine, American Otological Association, American Laryngological, Rhinological and Otological Society; and American Academy of Ophthalmology and Otolaryngology; surgeon to the ear, nose and throat department of Rhode Island Hospital, Providence; and aural surgeon on that staff; well-known as a specialist of diseases of the ear; died at his home in Providence, November 17, from septicemia, due to an operation wound, aged 44.

Frank Merriam Johnson, M.D. Albany (N. Y.) Medical College, 1898; a member of the Medical Society of the State of New York; and health officer of East Nassau, N. Y.; died at his home in that place, November 8, from the effects of a gunshot wound of the thorax, self-inflicted, it is believed, with suicidal intent, while ill and despondent, aged 40.

William J. Purkhiser, M.D. Kentucky School of Medicine, Louisville, 1882; a member of the Indiana State Medical Association, and secretary of the Third Councilor District Medical Society; in 1888 and 1889, senior assistant in the Central Indiana Hospital for the Insane, Indianapolis; local surgeon for the Monon System at Salem, Ind.; died in his office in that place, November 15, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health, aged 48.

William H. Finley, M.D. Medical College of Ohio, Cincinnati, 1858; assistant surgeon of the Twelfth Iowa Volunteer Infantry and surgeon of the Eighth Iowa Volunteer Cavalry during the Civil War; a member of the local pension board; coroner and commissioner of Dubuque county, Iowa, and a member of the common council of Cascade; died at his home, November 13, from senile debility, aged 78.

John H. Britts, M.D. Missouri Medical College, St. Louis, 1867; a member of the American Medical Association; surgeon in the Confederate Service during the Civil War; once mayor of Clinton, Mo., and state senator; died at his home in Clinton, November 13, aged 74.

Charles Henry Ott, M.D. Jefferson Medical College, Philadelphia, 1883; a member of the American Medical Association; superintendent and surgeon-in-chief to the Robert Packer Hospital, Sayre, Pa.; local surgeon to the Lehigh Valley Railroad; supreme medical examiner of the Modern Protective Association; died in the Robert Packer Hospital, November 1, from carcinoma of the liver, aged 48.

David Herrick Beckwith, M.D. Eclectic Medical Institute, Cincinnati, 1849; emeritus professor of sanitary science in the Cleveland Homeopathic Medical College; formerly president of the city and state boards of health; consulting physician to the Huron Street Hospital, Cleveland; vice-president of the Cleveland Medical Library Association; died at his home, November 19, aged 84.

Quincy Orlin Sutherland, M.D. Hahnemann Medical College, Chicago, 1873; a member of the Wisconsin State Board of Health, American Public Health Association, and Lake Michigan Sanitary Commission; at one time president of the board of education of Janesville, Wis.; died suddenly at his home, November 16, from angina pectoris, aged 61.

James William Stuart, M.D. Medical School of Maine, Brunswick, 1873; a member of the Maine Medical Association; formerly president of the Oxford County Medical Association; died at his home in Rumford Corner, November 10, from embolism, aged 65.

John Pierre Frishmuth, M.D. University of Pennsylvania, Philadelphia, 1890; of Philadelphia; a member of the American Medical Association; a specialist on diseases of the stomach, and formerly visiting physician to the American Hospital for Diseases of the Stomach; died in the University of Pennsylvania Hospital, Philadelphia, November 20, after two operations for tumor of the brain, aged 41.

Burr K. Ellis, M.D. University of Minnesota, Minneapolis, 1903; formerly of Jackson and Sparta, Minn.; and later of Greeley, Colo.; a member of the Colorado State Medical Society; died in Rock Valley, Iowa, November 4, from tuberculosis, aged 32.

Clifton Mayfield, M.D. George Washington University, Washington, D. C., 1880; a member of the American Medical Association; formerly of Washington, D. C.; died at his home in Canarsie, Long Island, N. Y., November 15, from heart disease, aged 51.

John Patrick Henry, M.D. New York University, New York City, 1886; a member of the American Medical Association, Physicians' Alliance, and Celtic Medical Society; died at his home in New York City, August 31, from neuritis, aged 50.

John Parker Powell, a pioneer practitioner of Oregon; for more than fifty years in practice in Gresham; for many years coroner of Multnomah county; died at his home in Gresham, October 30, from angina pectoris, aged 87.

John H. Seegraves, formerly of Rector, Ark.; assistant surgeon of volunteers during the Civil War; died at the home of his daughter in Mayfield, Ky., October 21, from malaria and acute articular rheumatism, aged 69.

John S. Cornwell, for more than sixty years a practitioner of Carthage, Tenn.; a surgeon in the Confederate Service during the Civil War; died at his home in Watertown, Tenn., July 28, from senile debility, aged 93.

Charles LeGrand Hayes, M.D. Vanderbilt University, Nashville, Tenn., 1877; a member of the Mississippi State Medical Association; died at his home in Byhalia, November 16, from cerebral hemorrhage, aged 50.

R. Augustus Evans, M.D. Western University, London, Ont., 1905; councilor for the town of Sutherland, Sask.; died in the General Hospital, Saskatoon, Sask., November 2, from chronic interstitial nephritis, aged 29.

Jay Judson Thompson, M.D. Chicago Homeopathic Medical College, 1888; professor of surgery in Hering Medical College, Chicago; died at his home in that city, November 22, from cerebral hemorrhage, aged 52.

Nathaniel Williams, M.D. University of Pennsylvania, Philadelphia, 1868; a surgeon in the Confederate Service during the Civil War; died at his home in Hampton, Va., November 18, from heart disease, aged 66.

William J. Chittenden (license, Ill., 1877; license, Colo., 1894); a veteran of the Civil War; died at the home of his daughter near Neodesha, Kan., May 15, from gastrointestinal catarrh, aged 68.

A. L. Holliday (license, Marshall county, Ala.); for more than thirty years a practitioner of Albertville, Ala.; died at the home of his son in Fairview, Birmingham, Ala., November 16, aged 75.

Cortez Nelson, M.D. Long Island College Hospital, Brooklyn, N. Y., 1908; a surgeon on South American steamers; died in Bellevue Hospital, New York City, November 1, from tropical fever, aged 45.

John Washington Shell (license, Iowa, 1895); for more than forty years a practitioner of Iowa; died at his home near Decatur, March 16, from cerebral hemorrhage, aged 85.

Rawdon J. Arnold, M.D. Kansas City (Mo.) Hospital Medical College, 1883; (license, Cal., 1877); of Oakland, Cal.; died in the Alameda County Hospital in April.

John M. Cooper, M.D. Medical College of Ohio, Cincinnati, 1857; of Wellsburg, W. Va.; died at the home of his daughter in Charleston, W. Va., November 17, aged 77.

John Thomas Fleming, M.D. Baltimore (Md.) Medical College, 1904; died at his home in Pascoag, R. I., November 11, from heart disease, aged 35.

Samuel Martin Kelso, M.D. Jefferson Medical College, Philadelphia, 1868; died at his home in Xenia, Ohio, October 17, from heart diease, aged 71.

Rodney F. Crowther, M.D. Baltimore (Md.) Medical College, 1883; died at his home in Earleigh Heights, Md., July 27, from senile debility, aged 84.

Dennis J. McLaughlin, M.D. University of Pennsylvania, Philadelphia, 1880; died at his home in Philadelphia, November 11, aged 52.

Lebbeus Curtis, M.D. Dartmouth Medical School, Hanover, N. H., 1878; died at his home in Hephzibah, Ga., November 16, aged 63.

Nathaniel C. Whitfield, M.D. Hahnemann Medical College, Chicago, 1883; died at his home in Los Angeles, November 7, aged 66.

Marriages

Elisha Flagg, M.D., to Mrs. Hugh Whitney, both of Boston, November 17.

William A. Dorsey, M.D., Seattle, Wash., to Miss Blanche Pentz, at Seattle, November 12.

Carroll Leja Nichols, M.D., to Miss Hazel Louisa Howe, both of Brooklyn, N. Y., November 2.

Robert L. Mitchell, M.D., Baltimore, Md., to Miss Annie Inskip Smith, of Elkton, Md., November 17.

Edwin Dixon Carder, M.D., to Miss Barbara Fraser Maclennan, both of Vancouver, B. C., October 12.

Richard Henry Lawlor, M.D., Methuen, Mass., to Miss Catherine V. Murphy, of Boston, November 18.

John Wilson Somerville, M.D., Norfolk, Va., to Mrs. Louise Gay Stubbs, of Atlanta, Ga., November 17.

Karl Francis Little, M.D., Westwood, Cincinnati, to Miss Dona Tebbs, of West Harrison, Ohio, November 17.

Patrick William O'Brien, M.D., Toronto, Ont., to Miss Helena Margaret Graves, at London, Ont., October 26.

Herman Louis Kretschmer, M.D., to Miss Lucy North Barnett, both of Chicago, at Richmond, Ind., November 17.

Eugene Boykin Elder, M.D., to Miss Margaret Selena Borthwick, both of Macon, Ga., at Toronto, Ont., September 18.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RUHEMANN'S URICOMETER

To the Editor:—Please answer the following questions regarding the workings of Dr. F. Ruhemann's uricometer. The normal marking on the scale is said to be 0.65; suppose that the reaction is not complete until the instrument is filled to the top, 0.25; then subtracting 0.25 from 0.65 we have 0.40. I take it that 0.40 means so much less than the urine should contain, but I would like to have you show how, with 0.40 to start with one can figure out the amount of uric acid the person is passing in 1,500 c.c. of urine. Kindly take some marking which shows that too much uric acid is being passed and work out the problem of telling the amount of uric acid in 1,500 c.c. of urine. J. L. Tracy, Toledo, Ohio.

Answer.—The principle of Ruhemann's uricometer is that uric acid will absorb iodin. A definite amount of iodin is placed in the instrument in a solution composed of iodin, 1.5; potassium iodid, 1.5; alcohol, 15; water, 185.0. In the very bottom of the instrument is a quantity of carbon disulphid. The carbon disulphid dissolves the iodin with a brown color. The urine is added gradually with shaking after each addition. When all the iodin has been absorbed by the uric acid in the urine, the carbon disulphid will be colorless (one must stop with a faint pink color). The less the proportion of uric acid in the urine, the more urine must be added to decolorize the iodin solution. Consequently the scale is arranged with markings for cubic centimeters on one side and amount of uric acid per thousand of urine on the other. The percentage of uric acid necessarily decreases with the increased amount of urine, so that the scale for amounts of uric acid reads from above downward. If 7.2 c.c. of urine must be added, a percentage of uric acid corresponding to 0.25 per thousand would be indicated. If the patient is passing 1,500 c.c. of urine this would amount to 0.375 gm. of uric acid. Suppose that it required the addition of only 4 c.c. of urine, the corresponding figure in uric acid would be 0.8 per thousand and the amount for 1,500 c.c. would be 1.2 gm. A normal marking on the scale is only an estimate, as what is normal in one case might be abnormal in another and this figure has nothing to do with the calculation except that if 0.65 is marked as the normal, we would calculate from that for 1,500 c.c. the normal quantity of uric acid as 0.975 gm.

The Public Service

Medical Department of the Army

Changes for the week ended Nov. 27, 1909:

Stark, Alexander N., major, granted an extension of 15 days to his leave of absence.

Duncan, William A., capt., granted sick leave of absence for 3 months.

Manly, Clarence J., major, granted leave of absence for 7 days.

Roberts, William M., major, promoted from captain November 17, vice Ewing, retired.

Glennan, James D., and Rafferty, Ogden, majors, ordered to report at Washington, December 17, for examination for promotion.

McAndrew, Patrick H., capt., ordered to report at Washington, D. C., for examination for promotion.

Jordan, Edward H., and Davis, Oscar F., 1st lieuts., M. R. C., relieved from duty in Philippines Division; will sail for San Francisco, Cal., February 15.

Browne, Rhodric W., 1st lieut., M. R. C., ordered from Fort Monroe, Va., to Fort Niagara, N. Y., for temporary duty.

Ellot, Henry W., 1st lieut., M. R. C., granted an extension of 1 month to his leave of absence.

Henning, Oswald F., 1st lieut., M. R. C., ordered to active duty; will proceed to San Francisco, and sail January 5, for Philippine service.

Wells, Francis M., 1st lieut., M. R. C., relieved from duty at Fort Robinson, Neb., and ordered to Fort Apache, Ariz., for duty.

Medical Corps of the Navy

Changes for the week ended Nov. 27, 1909:

Brownell, C. D., surgeon, detached from the *Mississippi* and granted sick leave for 6 weeks.

Clifford, A. B., P. A. surgeon, detached from the Naval Hospital, Las Animas, Colo., and ordered to the *Albany*.

Public Health and Marine-Hospital Service

List of Changes for the seven days ended Nov. 24, 1909:

Irwin, Fairfax, surgeon, relieved from duty on U. S. Revenue Cutter *Thetis*, effective Nov. 22, 1909, and granted 1 month's leave of absence.

Parker, Herman B., P. A. surgeon, relieved from duty at Ellis Island, N. Y., and directed to Guayaquil, Ecuador, for duty in the office of the U. S. Consul.

Anderson, John F., P. A. surgeon, directed to proceed to Mexico City, on special temporary duty.

White, M. J., P. A. surgeon, directed to proceed to Flint, Mich., on special temporary duty.

Lloyd, Bolivar J., P. A. surgeon, on the arrival of Passed Assistant Surgeon Herman B. Parker, directed to proceed to New York, and report by wire to the bureau for further orders.

Lloyd, Bolivar J., P. A. surgeon, granted 1 month's leave of absence en route to United States.

Spratt, R. D., P. A. surgeon, leave of absence for 20 days from Nov. 17, 1909, amended to read from December 10.

Lyon, R. H., asst.-surgeon, granted 7 days' leave of absence from Nov. 14, 1909, under paragraph 191, Service Regulations.

Duke, B. F., acting asst.-surgeon, granted 25 days' leave of absence from Nov. 18, 1909.

Castro-Guitierrez, J. L., acting asst.-surgeon, granted 7 days' leave of absence from Nov. 18, 1909.

Hallett, E. B., acting asst.-surgeon, granted 3 days' leave of absence from Nov. 24, 1909.

Naulty, C. W., Jr., acting asst.-surgeon, granted 5 days' leave of absence from Nov. 24, 1909.

Schuster, B. L., acting asst.-surgeon, granted 3 days' leave of absence from Nov. 25, 1909.

Sinclair, A. N., acting asst.-surgeon, granted 15 days' leave of absence from Dec. 16, 1909.

Ward, J. LaBruce, acting asst.-surgeon, granted 10 days' leave of absence from Nov. 17, 1909.

Wilson, J. G., acting asst.-surgeon, granted 25 days' leave of absence from Dec. 2, 1909.

BOARD CONVENED

Board of medical officers convened to meet at the Marine Hospital, Baltimore, Nov. 29, 1909, for the purpose of conducting a physical examination of four cadets and three cadet-engineers of the U. S. Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon M. K. Gwyn, recorder.

Health Reports

The following have been reported to the Public Health Service, during the week ended Nov. 26, 1909:

SMALLPOX—UNITED STATES

Alabama: Montgomery, Nov. 6-13, 15 cases.
California: San Francisco, Oct. 30-Nov. 6, 1 case.
Illinois: Chicago, Nov. 6-13, 1 case.
Indiana: Muncie, Nov. 6-13, 2 cases.
Kansas: Kansas City, Nov. 6-13, 1 case.
Louisiana: New Orleans, Nov. 6-13, 2 cases, imported.
New York: Buffalo, Nov. 6-13, 1 case.
West Virginia: Wheeling, Oct. 30-Nov. 6, 1 case.

SMALLPOX—FOREIGN

China: Shanghai, Sept. 25-Oct. 2, 1 case, 1 death.
Ecuador: Guayaquil, Oct. 1-15, 1 case.
India: Bombay, Oct. 5-12, 1 death.
Italy: Naples, Oct. 23-30, 3 cases, 1 death.
Mexico: Monterey, Oct. 24-31, 1 death; Veracruz, Oct. 23-30, 2 deaths.
Russia: Odessa, Oct. 10-17, 4 deaths; Warsaw, Sept. 11-18, 6 deaths.
Spain: Barcelona, Oct. 18-25, 1 death.
Turkey: Constantinople, Oct. 17-24, 1 death.

YELLOW FEVER

Ecuador: Guayaquil, Oct. 1-15, 13 cases, 4 deaths.
Mexico: Merida, Oct. 30-Nov. 6, 1 case, 1 death.

CHOLERA

Germany: Allenstein district, Oct. 23-30, 1 case; Andreischken, 6 cases; Heydekrug district, 6 cases; Labiau, 3 cases; Skirwietell, 5 cases; Skopen, 3 cases.
India: Calcutta, Oct. 2-9, 11 deaths.
Siberia: Vladivostok, Oct. 4-16, 20 cases, 1 death.

PLAGUE

Ecuador: Guayaquil, Oct. 1-15, 56 cases, 16 deaths.
India, general, Oct. 2-9, 5,209 cases, 4,123 deaths; Calcutta, 5 deaths.
Venezuela: Caracas, Nov. 11, 2 cases, 2 deaths.
Zanzibar, Nov. 8. 1 case, 1 death.

Association News

HOTELS FOR ST. LOUIS SESSION

First Announcement Concerning Hotels—Wisdom of Securing Accommodations Early

The Subcommittee on Hotels, of the Committee on Arrangements for the next annual session of the American Medical Association, to be held in St. Louis, June 7-10, 1910, announces arrangements for hotels.

The Southern Hotel, selected as General Headquarters, is in the down-town district, in the center of the hotel district, and about fifteen minutes' car ride from the various section meeting places. Other hotels of the same rank in the down-town district are the Planters, the American, the Maryland, the Jefferson, and the Marquette. Other excellent hostelries down town are the St. James, the Laclede, the Madison, the Terminal, the Moser, the Stratford, and the Bozier, all of which have splendid accommodations.

In the other direction, and in the so-called residence area, are a number of first-class hotels. The Buckingham, the Buckingham Annex, the Washington, and the Hamilton are from ten to fifteen minutes' ride distant, while the Beers and the West End are in the immediate locality of the section meeting halls. All the hotels mentioned have from 200 to 400 rooms.

Mr. Lyman Hay, president of the Hotel Managers' Association has notified the committee that the regular rates will prevail, and has expressed the earnest desire of the hotel men to have all well satisfied.

The Coliseum, at which will be the Registration Bureau, the Scientific Exhibit, and the Commercial Exhibit, is half way from the down-town district to the group of Section meeting places.

As the crowds which attend a session of the American Medical Association usually tax the hotel capacity of the city in which the session is held, the committee is preparing a list of other and smaller hotels, as well as a splendid list of boarding houses and private homes, in order to care for the overflow.

Many reservations are already made and the hotels are prepared for all applications. The Committee on Hotels requests early application to these hotels from any who are particular about their accommodations. For example, a group from one community may desire adjoining reservations; two or more persons may desire rooms *en suite*, with bath adjoining, one may have a preference for some particular hotel. These and other arrangements are possible now, but may be difficult or impossible to obtain later, when all the best rooms and even all available accommodations in some hotels will be engaged.

Applications should be sent direct to the hotel and the hotel management will make the arrangements desired; but the Committee on Hotels will gladly render aid at any time, to have all satisfactorily located. Dr. Louis H. Behrens, Chairman of the Committee on Hotels, may be addressed at Times Bldg., St. Louis.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Newspapers Interested in Public Instruction

One of the most gratifying indications of awakening interest in the enlightenment of the public on medical and sanitary questions is the interest shown by some of our leading newspapers on this subject. Reference has previously been made in these columns to the New Orleans *Item* (The Jour-

NAL, July 31, 1909, liii, 399). In its issue of November 10, the *Item* says editorially, in part, in discussing the duty of the doctor as a public teacher:

"The medical man either takes it for granted that the world knows that he knows or he fears that a little knowledge placed in the hands of the multitude will prove a dangerous thing. He overlooks the great agencies for the spread of correct information among the people; he operates as an individual or in his local society or hospital and forgets that he is forgotten in turn by the world at large until he is called to attend a case of sickness. In many cases he is called when it is already too late to effect a cure. Every physician who is earnest and capable and who cherishes the ideals of the splendid profession which he practices, knows that medicine is still in its infancy. . . . He feels that the day will come when society will employ the scientific physician as it now employs its public school-teachers, its governors and mayors, its legislators, its judges, and its police force. He knows that just as science has improved on the breeding of apples and oranges, of wheat and corn and sugar-cane, of horses and cattle and other animals, it will improve on the breeding and education of human beings. . . . We need an institute which will send out lecturers to spread a knowledge of hygiene among the children in the schools and among residents in the villages and country districts . . . that will collect and utilize every agency for the spread of a correct knowledge of preventable diseases. . . . The physician no more belongs to himself or to his class than does the preacher of the gospel, the teacher in the school, the publisher of a newspaper, the judge in the courts, or the advocate at the bar. As a professional man, it is his duty to serve humanity, to ask or demand the cooperation of other workers for the eliminations of wrong and the advancement of right in the service of humanity."

Equally gratifying is an editorial in the St. Louis *Republic* for November 17, called forth by letters to the editor from several antivaccinationists who advanced the stock arguments and time-worn statistics which have so often done duty on this subject. The *Republic* prints these letters in its correspondence columns and comments as follows editorially: "To defend vaccination gives a modern newspaper a queer sort of feeling. It is like defending the theory of the circulation of the blood or arguing with Rip Van Winkle, but it is still necessary, as two letters printed elsewhere on this page attest." The *Republic* then discussed the letters in question in a way that cannot fail to be enlightening and convincing to its readers.

The value of such comments lies in the fact that, coming from a layman and not a medical man, there can be in them no suspicion of personal interest such as is often injected into such discussions. When a newspaper like the St. Louis *Republic*, of its own initiative, defends and champions the cause of scientific medicine so convincingly and satisfactorily, it is certainly safe to assume that general public opinion is equally ready to support and to further sanitary reforms whenever the people are properly instructed.

Hogs Versus Children

The *Bulletin of the Iowa State Board of Health* recently contained the following item which graphically sets forth the apparent relative importance of children and hogs if one is to judge from the government appropriations made for their safety:

"Congress has been asked this year for an appropriation of $3,000 for the employment of an expert in the welfare of children. It was hoped by those who made the request that this modest beginning would lead to an efficient bureau of the Department of the Interior which would eventually deal with a wide range of questions affecting school children.

"In support of this request a Nebraska woman wrote that her husband was engaged in raising hogs while she was trying to raise a boy. Her husband, she said, had no difficulty in getting efficient and expensive aid from the government in his hog-raising pursuits, but she had to struggle along in her own way with the boy question. With a pardonable mother's prejudice, she argued that the welfare of her boy seemed almost as important as the health and happiness of her husband's hogs."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—Second Weekly Meeting

CHRONIC ENDOCERVICITIS

PATHOLOGY: 1. Erosion of cervical epithelium, (a) simple, (b) papillary or granular erosion. 2. Glandular enlargement, (a) polypoid (mucous polypi), (b) cystic (follicular) glandular enlargement.

DIAGNOSIS AND PROGNOSIS.

TREATMENT: Indications for local treatment, for repair of laceration, for amputation of cervix.

CHRONIC ENDOMETRITIS

CLASSIFICATION: A. Histological: 1. Glandular, (a) hypertrophic, (b) hyperplastic. 2. Interstitial. 3. Glandular and interstitial. Cystic and polypoid endometritis. B. Clinical: 1. Post-abortum. 2. Exfoliative. 3. Senile. 4. Bacterial (tubercular, gonorrheal, typhoid, etc.). 5. Decidual.

SYMPTOMS: Menstrual disturbances, hemorrhages, discharge, abortions or sterility, pain, vesical and rectal disturbances, systemic and reflex disorders.

TREATMENT: Systemic, local, surgical.

CHRONIC METRITIS

PATHOLOGY: Chronic changes in endometrium; in peritoneum; in muscularis, 1. hypertrophic, (a) puerperal (subinvolution), (b) nonpuerperal (elongation of cervix); 2. interstitial, cirrhotic, metritis (puerperal and non-puerperal atrophy).

SYMPTOMS AND DIAGNOSIS.

PELVIC INFLAMMATION

Includes metritis, lymphangitis, phlebitis, cellulitis, salpingitis, ovaritis and pelvic peritonitis.

ROUTES OF INFECTION: Extension by (a) continuity of uterine and tubal mucosa, (b) through lymph and blood vessels, (c) extension from extrapelvic organs, appendicitis, tubercular peritonitis, etc.

ETIOLOGY: Secondary to endometritis, traumatisms of parturition and surgery, vaginal, vesical, intestinal and peritoneal infections, acute infectious diseases. Micro-organisms present, relation of different organisms to extent and character of pathology.

Society Proceedings

COMING MEETINGS

American Physiological Society. Washington, D. C., December 28-30.
Medical Society of State of New York, Albany, January 25.
Southern Surg. & Gynecological Assn., Hot Springs, Va., Dec. 20-21.
Western Surgical and Gynecological Assn., Omaha, December 20-21.

CITY OF WASHINGTON BRANCH OF THE AMERICAN PHARMACEUTICAL ASSOCIATION

Meeting held November 3, 1909

DR. H. W. WILEY, Chief of the Bureau of Chemistry, in the Chair

Patent and Trade-Mark Laws

The audience included pharmacists, physicians, manufacturers and representatives of at least several government services, including the Patent Office and the Bureau of Chemistry.

DR. MURRAY GALT MOTTER, Washington, discussed the report of the Committee on Patents and Trade-Marks of the American Medical Association (THE JOURNAL A. M. A., June 19, 1909, p. 2063), and pointed out that this report presented the several questions in a clear and concise manner.

DR. F. E. STEWART, Philadelphia, a member of the Committee on Patents and Trade-Marks of the *American Pharmaceutical Association*, discussed the report of his committee.

MR. SAMUEL L. HILTON, Chairman of the *Committee* on National and State Legislation of the American Pharmaceutical Association, reported on the hearings on the Mann bill and outlined the history of that bill. He pointed out the shortcomings of that particular measure and the possibility of overcoming them by modifications.

Mr. Willard S. Richardson, Chairman of the Committee on National Legislation of the N. A. R. D. reported on the hearings that have been held on the Currier bill. He said in part: The purpose of this bill was to bring about a more equitable exchange of patent rights between this country and foreign countries. At present, a citizen of a foreign country receives more protection by a patent in this country than is given in a foreign country to an American citizen. This humiliating condition is generally unknown to the majority of American citizens. The only objection that has ever been urged against the reciprocal principle of the Currier bill is that the adoption of this principle would be in opposition to Article 2 of the International Agreement of 1883. Since that agreement, a number of foreign countries have introduced serious and unjust restrictions, to the detriment of American citizens. At the Brussels Conference, in 1887, our delegates endeavored to secure a modification of Article 2. While we lost in our contention no criticism was ever attempted on the stand taken by us. President Roosevelt, in his message in 1903, said: In granting patents to foreigners, the proper course for this country to follow is to give the same advantages to foreigners that the country in which these foreigners live extends in return to our citizens. Even the attorneys who have been opposing any change in the present patent laws have not denied the justice of the principle embodied in the Currier bill, and all their efforts have been centered on delaying action of any kind by prolonging the hearings and begging for delay on the ground that the matter should not be gone over hastily.

Dr. Worth Hale, of the Public Health and Marine-Hospital Service, pointed out that, in speaking of the misuse of drugs as fostered by our patent and trade-mark laws, one should disregard personal and financial considerations, since the whole question rests ultimately on such factors as will bring the greatest degree of health to those who suffer from disease. The patient's right and his protection are first to be considered; the interest of manufacturers, of physicians and of pharmacists are but secondary and are to be considered only after the welfare of the general public has been safeguarded. In whatever degree patent and trade-mark laws have lessened this protection they are to be criticized adversely.

Because of laws giving to manufacturers exclusive rights to names and products, the pharmacies of every city and village in the United States are filled with inferior, useless and harmful medicinal substances, and pharmacies frequently have in stock, because of special nomenclature, five, ten, possibly twenty, duplications of the same chemical substance or pharmaceutical mixture. A well-known instance of this abuse is evidenced by hexamethylenamin, the duplication of which has become a necessity in order to meet the demand of the physician who orders it under a trade name, because he is ignorant of its true composition.

We must remember, however, that the abuses which exist have not developed because of the existence of patent and trade-mark laws, but because of the advantages taken of the privileges accorded by them. It must be admitted that patent and trade-mark laws permit of the establishment of monopolies, a monopoly fosters unusual profits, unusual profit permits of extensive advertising, extensive advertising increases the sale, and consequently the use or abuse, thus making the financial returns from the protected product both certain and large. It is unfortunate, indeed, that in no other field are extravagant misleading and unverified claims so difficult to correct or control as in connection with medicinal products, whether advertised to the medical profession or to the laity; whether the remedy be peruna or purgen, dysmenorrhets or desiccated castor oil, its successful sale depends far more on the advertising claims made for it than on absolute or comparative value over older preparations. The advertising pages of even the better class of medical journals are filled with statements that are designed to mislead, are always exaggerated, and not infrequently positively untrue. Just a few instances taken at random:

"Syrup Roborans, as a nerve stimulant and restorative in wasting and debilitating diseases, as a constructive agent in insomnia, pneumonia, tuberculosis, bronchial asthma, marasmus, strumous diseases and general debility this compound has no equal."

"Tongaline, successfully prescribed for twenty-five years. Rheumatism, neuralgia, sciatica, lumbago, malaria, grippe, colds, gout, excess of uric acid. Relieves pain, allays fever, eliminates poison, stimulates recuperation."

"Verily it hath become too easy to live."

The shame of it is that such statements are believed and that they are believed is evidenced by the fact that they must bring returns or they would not be made. No arraignment of modern advertising methods and of the physician who has been influenced by them can be too severe, for the commercial spirit thus generated has robbed medicine of its best heritage, a materia medica based on scientific principles, and has left in its place, at least with the physicians affected, a materia medica of monopolized preparations prescribed by "Docs" educated by detail men and the "patent-medicine" literature of the manufacturer.

Prof. John Uri Lloyd, Cincinnati, pointed out that he necessarily differed from many of his friends on some of the questions that had been under discussion, and asserted that we must individually live up to what we consider to be right and just. He discussed the application and the possible uses of copyrights, trade-marks and patents and expressed himself as being opposed to the granting of product patents because this practice tends to prevent the development of science and is therefore unfair and unjust. He controverted some of the arguments that had been used in connection with the opposition to the Mann bill, and expressed himself as being hopeful of the enactment of more equitable patent laws in the near future. He also expressed himself as having an abiding faith in the pharmacy of the future and in the development of the sciences of pharmacognosy and pharmacology. He also has hope in the materia medica of the future, and expects to witness the elimination of heroic drugs from which so many people at the present time do not escape.

Dr. H. W. Wiley pointed out some of the abuses that had been exposed by the work of the Council on Pharmacy and Chemistry of the American Medical Association, and asserted that the duplication of names for the same, or practically the same, substance constitutes an abuse of far-reaching influence. He pointed out that medical men are gradually recognizing the fallacy of expecting to secure what might be termed mass effect by the use of complex mixtures, and that the trend at the present time is to prescribe simple medicaments for the purpose of securing definite effects.

Mr. M. I. Wilbert pointed out that the reference made by Professor Lloyd to the use of "heroic drugs from which so many of our people do not escape," was particularly applicable to the widespread use, or more correctly, abuse of the so-called synthetic preparations. He expressed himself as fearful that when the history of the tar barrel was finally written, as it eventually will be, the harm done by these remedies, the lives that have been materially shortened and the constitutions that have been undermined, will far outweigh any real good that has been evidenced up to the present time.

Mr. Wymond H. Bradbury called attention to some of the petty frauds that have been developed in connection with patents on medicinal products and referred at some length to the practice of the American agents for some of the products on which patents have expired, who, as is well known, are asking a much higher price for phenacetin, sulphonal and trional, as such, than for the corresponding substances sold by them under the official titles, though there is no detectable difference in the quality of the article, and there is every reason to believe that the agents themselves import these substances under their official titles and pay the minimum import duty.

The continued proprietorship in the name of a patented article, after the expiration of the patent, was further discussed by Dr. Stewart, Dr. Seaman and Mr. Hilton, the latter expressing the belief that the quibble over the property right in the name of a patented medicinal article had never arisen until in connection with phenacetin, sulphonal and trional.

Book Notices

NAVAL HYGIENE. By James Duncan Gatewood, M.D., Instructor in Naval Hygiene, United States Naval Medical School, Washington. Cloth. Pp. 779, with 113 illustrations, 8 colored. Price, $6 net. Philadelphia: P. Blakiston's Son & Co., 1909.

Surgeon Gatewood, from his long experience in the navy and in this especial line, is well fitted to prepare a text-book on naval hygiene. He first takes up naval vital statistics, which he considers the basis of the navy's hygiene, and the air within and without the ship, and in these includes the diseases of seafaring people, which are largely due to lack of proper adjustment between the spaces in the ship and the air and water. The author then considers the matter of light without and within the ship, including illumination, absorption, and reflection of light, the color of clothing in the tropics, etc.; the ship's water and drainage; the hardness of water and its reduction; lavatory arrangements on ships; the storage of water; water distillation, analysis of water; purification of water; camps and camp sites. The chapter on the food of the navy is especially well illustrated with colored plates, showing the natural appearance of healthy beef. A number of illustrations of various edible fish, which take up considerable space, are inserted for some incomprehensible reason. In this chapter is taken up the matter of the proper balance of ration, its determination or analysis, the ideal diet in the tropics, and the care of foods. The navy's clothing, the question of clothing in relation to the body temperature is next discussed; education of the skin, chemical regulation of temperature; conductivity of clothing materials; the respective benefits of wool, linen and cotton; the value of dry clothing; night clothes, uniforms, the care of clothing, etc. Disinfection of the ship is naturally a very important question, and is well and fully considered. The vital causes of disease are detailed; disinfection, isolation to prevent lines of travel; value of disinfectants, and the various communicable diseases expected to be met with on shipboard. Dr. Gatewood also discusses insecticides and the various disinfectants. An entire chapter is devoted to naval recruiting. This deals with the method of making examinations of recruits; the requirements for success in selecting recruits; the object of medical examination in recruitment, and the standardization of the recruit and of the examiner.

MYELOISCHE METAPLASIE UND FÖTALE BLUTBILDUNG UND DEREN HISTOGENESE. Von Dr. med. Heinrich Fischer, Sanatorium "Untere Waid" bei St. Gallen (Schweiz). Paper. Pp. 140. Price, 4 marks. Berlin: Verlag von Julius Springer, 1909.

The facilities which German investigators have for putting out their more extensive publications in the form of monographs is a source of envy to their American colleagues. Technical and medical journals can not afford to turn over the necessary amount of space for this sort of article, while to attempt to publish independently would be almost inevitably ruinous. In Germany, however, it seems to be possible to float almost any publication, however technical, provided it has merit. Fischer's monograph of 140 pages is one of this class.

In certain conditions we find that organs among whose functions we do not ordinarily consider formation of leucocytes and erythrocytes have taken on this function in circumscribed cellular areas which spring up in various places. This "myeloid metaplasia" we associate especially with leukemia, the finding of so-called lymphoid nodules in the liver and elsewhere being a familiar observation. As Fischer shows, however, this peculiar sort of atavism of tissues, whereby they revert to their fetal character of blood-forming organs, is observed to greater or less degree in sundry conditions besides the typical blood diseases. This myeloid metaplasia was ascribed by Neumann and Ehrlich to a metastasis of cells from the bone-marrow, since this was recognized as the only place in which such blood-forming cells were normally present, a view which has long remained prevalent because of the authority of Ehrlich. Other investigators have, however, brought forward evidence that the myeloid cells were not necessarily metastatic but might be present in many tissues as the result of metaplasia of the fixed tissue cells, and M. B. Schmidt in particular demonstrated that the endothelial cells of the liver may manufacture both white and red corpuscles.

Fischer reviews systematically and effectively the facts and theories that bear on both the normal and pathologic formation of blood cells, and then recounts his own observations. These lead him to the conclusion that the view that foci of hematogenic activity in the tissues do not arise through metastasis of marrow cells, but by metaplasia of connective tissue cells especially, and possibly also from endothelial cells. Many interesting observations are recorded concerning other than this main problem, and the pamphlet is of considerable value to hematologists and pathologists.

WALSH'S PHYSICIANS' COMBINED CALL-BOOK AND TABLET. Flexible leather, with flap and pocket. Price, $1.50. Washington, D. C.: Ralph Walsh, M.D., 1804 H Street, N. W.

The usual physicians' visiting list has been modified by Walsh so that it may also be used as a ledger. It contains much useful information; a very concise clinical table of the eruptive fevers, a table showing the changes in strength of important tinctures made official by the last U. S. Pharmacopeia; a complete dose-table for adults; poisons and their antidotes; diet list; the use of the thermometer; facts about infants, etc. The book is of the usual size and is arranged for a monthly record. Pages for memorandum, addresses, obstetric records, and a cash account, are included.

A TEXT-BOOK OF PHYSIOLOGIC CHEMISTRY. By John H. Long. M.S., Sc.D., Professor of Chemistry in Northwestern University Medical School, Chicago. Second Edition. Cloth. Pp. 396, with 42 illustrations. Price, $2.50 net. Philadelphia: P. Blakiston's Son and Co., 1909.

The second edition of this text-book presents some important changes, including the new protein classification adopted by the American societies and a much fuller discussion of the subject of the urine with a new chapter on the methods of urine analysis. The book gives a very clear statement of the chemical facts which should be required in medical schools, while omitting the details which are of interest only to specialists. Long appreciates the danger of presenting more to the student than the student has time to master properly, and a careful examination of the work shows that this danger has been successfully avoided. This new edition will be welcomed both by teachers and students.

THE BLOOD IN HEALTH AND DISEASE. By R. J. M. Buchanan, M.D., F.R.C.P., Professor of Forensic Medicine in the University of Liverpool. Cloth. Pp. 318, with illustrations. Price, $4.50. New York: Oxford University Press, 1909.

This book is evidently prepared to meet the requirements of medical students, but it is, like so many other text-books, not flattering to the ideals of this class of humanity. It is a perfectly good synopsis of the subject of hematology, but there is nothing about it to interest or stimulate the average student, and it will not satisfy the better type of student who wishes to know something of the evidence before he accepts conclusions. Such a book—and there are many not so good as this one—may have a certain field of usefulness and satisfy the demands and desires of many students, but instructors with progressive ideas as to medical education do not exult at their publication. This particular hematology is at its best in the discussion of the changes in the blood in the diseases studied most commonly by the routine methods of the clinical laboratory; with other conditions Dr. Buchanan seems less familiar, and much of recent progress in medical science is disregarded and superseded views are quoted as if established facts. For example, the occurrence of the pneumococcus in the blood in pneumonia is referred to as if occasional, and of grave prognostic import; although it has been abundantly shown, especially by Rosenow, that pneumococcemia is practically constant in pneumonia, J. H. Wright's observations on the origin of the blood platelets are not mentioned, and many similar omissions might be recorded. The book is embellished with many excellent reproductions of careful colored drawings of blood preparations made by Dr. Buchanan, and in general, the publisher's part of the work is exceptionally well done.

Neurasthenia. By Gilbert Ballet, Professor *agrégé* at the College of Medicine of Paris. Translated from the Third French Edition by P. Campbell Smith, M.D. Cloth. Pp. 408, with 7 illustrations. Price, $2 net. New York: Paul B. Hoeber, 1909.

Precisely at this time, while the epidemic of psychotherapeutic "afflictions" is still raging in and out of the profession, Professor Ballet's book on neurasthenia is opportune. Primarily designed as a monograph on treatment, the present (third) edition, of which this is an excellent translation, has expanded so as to include etiology and symptomatology. To those who received their first psychotherapeutic repast out of Dubois' milk-bottle, this book may seem more difficult of digestion, but in the end it will be found more invigorating and real food for men. The volume is replete with good advice and will be profitable alike to specialist and general practitioner.

Though the bulk of the book is devoted to treatment, yet the preliminary short chapters on etiology, symptomatology and classification deserve commendation, as they are clear and conform to the accepted views of neurologists both here and abroad. Unlike Dubois' book, which is a combination of metaphysics, pseudopsychology and psychotherapy, it gives facts and does not confuse the reader by placing hysteria, neurasthenia, psychasthenia, hypochondriasis and every other classified and unclassified nervous trifle under the all-comprehensive head of neurosis and treating them all as one disease. Ballet distinguishes two great types of neurasthenia, (1) the so-called neurasthenia minor, found in childhood and manifesting itself by congenital tendencies to physical weakness and mental insufficiencies, and (2) the fully developed neurasthenia of adults, characterized by exhaustion and irritability, which variety he calls neurasthenia major. This classification is similar to that of Dercum, who calls the form which correspond to Ballet's "neurasthenia minor," "neurasthenoid," that is a condition like neurasthenia, but really belonging to various other psychoses or degenerative neuroses, while Ballet's "neurasthenia major" he considers true neurasthenia and treats it very much as Ballet does—as a physical, not a mental affection.

The chapters on treatment are good. Due credit is given to psychotherapy, but the greatest emphasis is put on the treatment of physical conditions, which we believe proper. In a similar sense Oppenheim has recently answered Dubois in a German publication. Neurasthenia is treated not only by suggestion and persuasion for any existing psychic symptoms which may have developed on the physical disorder, but also by means of electricity, massage, hydrotherapy, the rest-cure, dietetic and climatic treatment, and, last of all, by means of drugs to combat certain visceral symptoms. Ballet is no fanatic and does not offer a panacea for all forms of neurasthenia. Among the many excellent chapters the one on diet, which treats of the various digestive disturbances of neurasthenics, is one of the best and well worth careful study. The book is written in an easy style and adapted to the practitioner's needs.
